Integrity constraints for a relational database schema

- **1. Domain constraint**
  - attribute values for attribute A shall be atomic values from dom(A)
- **2. Key constraint**
  - candidate keys for a relation must be unique
- **3. Entity integrity constraint**
  - no primary key is allowed to have a null value
- **4. Referential integrity constraint**
  - a tuple that refers to another tuple in another relation must refer to an existing tuple
- **5. Semantic integrity constraint**
  - e.g. “an employee’s total work time per week can not exceed 40 hours for all projects taken all together”
Domain constraints

- Integrity constraints guard against accidental damage to the database, by ensuring that authorized changes to the database do not result in a loss of data consistency.
- Domain constraints are the most elementary form of integrity constraint.
- They test values inserted in the database, and test queries to ensure that the comparisons make sense.
Domain constraints cont…

- The **check** clause in SQL-92 permits domains to be restricted:
  - Use check clause to ensure that an hourly-wage domain allows only values greater than a specified value.
  
  ```sql
  create domain hourly-wage numeric(5,2) constraint value-test check( value >= 4.00)
  ```

  - The domain hourly-wage is declared to be a decimal number with 5 digits, 2 of which are after the decimal point
  - The domain has a constraint that ensures that the hourly-wage is greater than 4.00.
  - The clause constraint value-test is optional; useful to indicate which constraint an update violated.
Referential integrity

• Ensures that a value that appears in one relation for a given set of attributes also appears for a certain set of attributes in another relation.
  – Example: if “Perryridge” is a branch name appearing in one of the tuples in the account relation, then there exists a tuple in the branch relation for branch “Perryridge”.

• Formal definition
  – Let \( r_1(R_1) \) and \( r_2(R_2) \) be relations with primary keys \( K_1 \) and \( K_2 \) respectively.
  – The subset \( \alpha \) of \( R_2 \) is a foreign key referencing \( K_1 \) in relation \( r_1 \), if for every \( t_2 \) in \( r_2 \) there must be a tuple \( t_1 \) in \( r_1 \) such that \( t_1[K_1] = t_2[\alpha] \).
  – Referential integrity constraint: \( \Pi_\alpha(r_2) \subseteq \Pi_{K}(r_1) \)
Referential integrity in the E-R model

- Consider relationship set $R$ between entity sets $E_1$ and $E_2$.
- The relational schema for $R$ includes the primary keys $K_1$ of $E_1$ and $K_2$ of $E_2$.
- Then $K_1$ and $K_2$ form foreign keys on the relational schemas for $E_1$ and $E_2$ respectively.
- Weak entity sets are also a source of referential integrity constraints. The relation schema for a weak entity set must include the primary key of the entity set on which it depends.
Database modification

- The following tests must be made in order to preserve the referential integrity constraint: \( \Pi_\alpha(r_2) \subseteq \Pi_K(r_1) \)
- **Insert.** If a tuple \( t_2 \) is inserted into \( r_2 \), the system must ensure that there is a tuple \( t_1 \) in \( r_1 \) such that \( t_1[K_1] = t_2[\alpha] \). That is \( t_2[\alpha] \in \Pi_K(r_1) \)
- **Delete.** If a tuple \( t_1 \) is deleted from \( r_1 \), the system must compute the set of tuples in \( r_2 \) that reference \( t_1 \):
  \[
  \sigma_\alpha = t_1[K_1](r_2)
  \]
  If this set is not empty, either the delete command is rejected as an error, or the tuples that reference \( t_1 \) must themselves be deleted (*cascading deletions are possible*).
Database modification cont’d

- **Update.** There are two cases:
  - **Case 1:** If a tuple \( t_2 \) is updated in relation \( r_2 \) and the update modifies values for the foreign key \( \alpha \), then a test similar to the insert case is made. Let \( t_2’ \) denote the new value of tuple \( t_2 \). The system must ensure that:
    \[ t_2’[\alpha] \in \Pi_{K_1}(r_1) \]
  - **Case 2:** If a tuple \( t_1 \) is updated in \( r_1 \), and the update modifies values for the primary key \( (K_1) \), then a test similar to the delete case is made. The system must compute \( \sigma_{\alpha} = \Pi_{K_1}(r_2) \) using the old value of \( t_1 \) (the value before the update is applied). If this set is not empty, the update may be rejected as an error, or the update may be cascaded to the tuples in the set (*cascading update*), or the tuples in the set may be deleted (*cascading delete*).
Referential integrity in SQL

- Primary and candidate keys and foreign keys can be specified as part of the SQL `create table` statement:
  - The `primary key` clause of the `create table` statement includes a list of the attributes that comprise the primary key.
  - The `unique key` clause of the `create table` statement includes a list of the attributes that comprise a candidate key.
  - The `foreign key` clause of the `create table` statement includes both a list of the attributes that comprise the foreign key and the name of the relation referenced by the foreign key.
Referential integrity in SQL - example

```
create table customer
    (customer-name char(20) not null,
     customer-street char(30),
     customer-city char(30),
     primary key (customer-name))

create table branch
    (branch-name char(15) not null,
     branch-city char(30),
     assets integer,
     primary key (branch-name))
```
Referential integrity in SQL - example cont’d

```sql
create table account
  (account-number char(10) not null,
   branch-name char(15),
   balance integer,
   primary key (account-number),
   foreign key (branch-name) references branch)

create table depositor
  (customer-name char(20) not null,
   account-number char(10) not null,
   primary key (customer-name, account-number),
   foreign key (account-number) references account,
   foreign key (customer-name) references customer)
```
Cascading actions in SQL

```sql
create table account

... foreign key (branch-name) references branch
    on delete cascade
    on update cascade,

...)```

- If a tuple in `branch` is deleted (updated), there is a tuple in `account` that will also be deleted (updated), i.e. the delete (update) cascades.
Cascading actions in SQL cont’d

• If there is a chain of foreign-key dependencies across multiple relations, with on delete cascade specified for each dependency, a deletion or update at one end of the chain can propagate across the entire chain.

• If a cascading update or delete causes a constraint violation that cannot be handled by a further cascading operation, the system aborts the transaction. As a result, all the changes caused by the transaction and its cascading actions are undone.
Assertions

• An **assertion** is a predicate expressing a condition that we wish the database always to satisfy.

• An assertion in SQL-92 takes the form:
  
  ```sql
  create assertion <assertion-name> check <predicate>
  ```

• When an modification (insert/delete/update) of the db is made, the system tests it for validity. This testing may introduce a significant amount of overhead; hence assertions should be used with great care.
Assertion example

- The sum of all loan amounts for each branch must be less than the sum of all account balances at the branch.

```sql
create assertion sum-constraint check
  (not exists
    (select *
      from branch b
    where (select sum(amount)
      from loan
      where loan.branch-name =
        b.branch-name) >=
    (select sum(amount)
      from account
      where account.branch-name =
        b.branch-name)))
```
Another assertion example

- Every loan has at least one borrower who maintains an account with a minimum balance of $1000.00.

```
create assertion balance-constraint check  
    (not exists  
    (select *  
    from loan  
    where not exists  
    (select *  
    from borrower, depositor, account  
    where loan.loan-number = borrower.loan-number and  
    borrower.customer-name = depositor.customer-name and  
    depositor.account-number = account.account-number and  
    account.balance >= 1000)))
```
