Abstract

In this paper, we study structural and spectral features of linear systems of equations arising from Galerkin approximations of \( H(\text{curl}) \) elliptic variational problems, based on the Isogeometric Analysis (IgA) approach. Such problems arise in Time Harmonic Maxwell and magnetostatic problems, and lead to large linear systems, with different and severe sources of ill-conditioning.

First, we consider a Compatible B-Splines discretization based on a discrete De Rham sequence and we study the structure of the resulting matrices \( A_n \). It turns out that \( A_n \) shows a two-by-two pattern and is a principal submatrix of a two-by-two block matrix, where each block is two-level banded, almost Toeplitz, and where the bandwidths grow linearly with the degree of the B-splines.

Looking at the coefficients in detail and making use of the theory of the Generalized Locally Toeplitz (GLT) sequences, we identify the symbol of each of these blocks, that is a function describing asymptotically, i.e., for \( n \) large enough, the spectrum of each block. From this spectral knowledge and thanks to some new spectral tools we retrieve the symbol of \( t A_n t^* \), which as expected is a two-by-two matrix-valued bivariate trigonometric polynomial. In particular, there is a nice elegant connection with the continuous operator, which has an infinite dimensional kernel, and in fact the symbol is a dyad having one eigenvalue like the one of the IgA Laplacian, and one identically zero eigenvalue: as a consequence, we prove that one half of the spectrum of \( A_n \), for \( n \) large enough, is very close to zero and this represents the discrete counterpart of the infinite dimensional kernel of the continuous operator. From the latter information, we are able to give a detailed spectral analysis of the matrices \( A_n \), which is fully confirmed by several numerical evidences.

Finally, by taking into consideration the GLT theory and making use of the spectral results, we furnish indications on the convergence features of known iterative solvers and we suggest proper iterative techniques for the numerical solution of the involved linear systems.

Keywords: Maxwell equations; compatible B-spline discretization; spectral distribution and spectral symbol; GLT matrix-sequence

1 Introduction

In many physics and engineering applications [3], the numerical discretization of electromagnetic problems and of the Maxwell equations is of critical importance. In real applications, for example the Full-Wave problem with high wave numbers, the numerical simulation of such problems leads to huge sparse and ill-conditioned matrices and therefore the use of direct solvers is not possible. Iterative solvers are then the only possible choice, but suffer from ill-conditioning, where the latter is either caused by some physical parameters or by the used numerical method or by a combination of the two components. Furthermore, the need of robust and optimal \textit{fast} solvers is motivated by the large-scale simulation codes and the architecture of modern super-computers. Such solvers have been extensively studied in the last two decades for standard discretization [14, 15, 17, 18]. However, the spectral behavior of the resulting matrices is very involved and not favorable, so that this affected the design
of fast and robust iterative solvers. In this direction, a valid alternative is represented by the Isogeometric Analysis (IgA): in fact, since its introduction [16], the IgA has proven to be a promising approach and, as for the Nodal Finite Elements case, it provides a discrete De Rham sequence [2]. However, by allowing the use of more regular basis functions, IgA-based matrices offer more favorable (spectral) properties compared to the case of Nodal Finite Elements methods (see the discussion at page 34 in [4] and the analysis of the spectral symbol for Finite Elements in [10]). In the case of maximum regularity, it turns out that we are able to describe easily the spectrum of the discrete operators, thanks to the Generalized Locally Toeplitz (GLT) theory [23, 7, 8, 9]. Moreover, IgA discretization can provide structured matrices and are then well adapted for the architecture of modern super-computers. Unfortunately, IgA is still a young topic and all the known results and developed methods for the standard discretizations are not yet available.

In this work, we are interested in the spectral study and analysis of the sequence of matrices corresponding to a compatible B-Splines discretization of the following variational problem

\[ u \in H(\text{curl}, \Omega) : \quad (\nabla \times u, \nabla \times v) + \mu (u, v) = (f, v), \quad \forall v \in H(\text{curl}, \Omega), \]

where \( f \) is a vector field in \((L^2(\Omega))^2\), \( \mu \geq 0 \), and

\[ H(\text{curl}, \Omega) := \{ u \in (L^2(\Omega))^2 \text{ s.t. } \nabla \times u \in L^2(\Omega) \}. \]

It is worth noticing that variational problems of the form (1.1) arise in different applications such as Time Harmonic Maxwell equation and magnetostatic problems (described by \( \mu = 0 \)), as well as Time Domain Maxwell equations and MagnetoHydroDynamics problems, when using an implicit time stepping.

We focus our attention on a IgA discretization of problem (1.1), where we restrict the study to a 2D problem with \( \Omega = [0, 1]^2 \), in which case, the \( \text{curl} \) operator has the explicit expression \( \nabla \times u = \partial_y u_x - \partial_x u_y \) for any \( u = [u^1(x, y), u^2(x, y)]^T \). Our first aim is to spectrally analyze the sequence of the resulting coefficient matrices and then to use such spectral information to suggest suitable iterative solvers for the corresponding linear systems.

First of all the global matrix \( A_n \) shows a two-by-two block structure and is a principal submatrix of a two-by-two block matrix, where each block is two-level banded, almost Toeplitz (i.e., Toeplitz up to small rank corrections), and where the bandwidths grow linearly with the degree of the B-splines.

After a careful study of the coefficients and making use of the theory of GLT sequences, we show that the four sequences containing these four Toeplitz-like blocks are all GLT sequences and we identify the symbol. According to Weyl, the symbol of a sequence of Hermitian (or quasi-Hermitian) matrices is a function describing asymptotically, i.e., for \( n \) large enough, the spectrum of the \( n \)-th matrix. From this knowledge and as a consequence of some new spectral tools we recover the symbol of \( \{A_n\}_n \) which as expected is a two-by-two matrix-valued bivariate trigonometric polynomial. We show a nice and elegant connection between the discrete structures and the continuous operator, which has an infinite dimensional kernel. In fact the symbol of the discrete structures is a dyad having one eigenvalue like the one of the IgA Laplacian, and one identically zero eigenvalue: as a consequence, we prove that one half of the spectrum of \( A_n \), for \( n \) large enough, is very close to zero and this represents the discrete counterpart of the infinite dimensional kernel of the continuous operator. Starting from these findings, we are able to furnish a detailed spectral analysis of the matrices \( A_n \), which are fully confirmed by several numerical evidences.

Furthermore, taking into account the GLT theory and exploiting the spectral results, we give indications on the convergence features of known iterative solvers and we suggest ad hoc iterative procedures for the numerical solution of the considered linear systems. Such a discussion is accompanied by a selection of numerical tests which are presented and critically discussed.

The overview of the paper is as follows. In Section 2 we give notations, definitions, and preliminary results. Section 3 is devoted to the IgA approximation of the variational problem reported in (1.1), by using B-splines, while in Section 4 we perform a detailed spectral analysis of the resulting matrices, by also providing new matrix-theoretic tools and by discussing few numerical tests, including algorithmic proposals (in Subsection 4.4) fully developed in a twin paper. Finally, in Section 5 we draw conclusions.

2 Notation and preliminaries

In this section we will introduce some preliminary approximation and spectral tools used in the whole paper. In detail, in Subsection 2.1 we will recall the definition of (cardinal) B-spline together with some relevant properties. Subsections 2.2, 2.3 are devoted to spectral notions of multilevel block Toeplitz matrices and of
GLT matrix-sequences, respectively. We will end this section collecting some spectral results on the matrices involved in the IgA discretization of 1D elliptic problems (Subsection 2.4), which will be widely used in the IgA discretization of the curl-curl problem discussed in Section 3.

2.1 B-splines and cardinal B-splines

For $p, n \geq 1$ consider the uniform knot sequence

$$t_1 = \ldots = t_{p+1} = 0 < t_{p+2} < \ldots < t_{p+n} < 1 = t_{p+n+1} = \ldots = t_{2p+n+1},$$

where

$$t_{i+p+1} = \frac{i}{n}, \quad i = 0, \ldots, n.$$

**Definition 2.1.** The B-splines of degree $p$ on the knots sequence (2.1) are denoted by

$$N^p_i : [0, 1] \rightarrow \mathbb{R}, \quad i = 1, \ldots, n + p,$

and are recursively defined as follows: for $1 \leq i \leq n + 2p$

$$N^0_i(t) = \chi_{[t_i, t_{i+1})}, \quad t \in [0, 1];$$

for $1 \leq k \leq p$ and $1 \leq i \leq n + 2p - k$

$$N^k_i(t) = \frac{t - t_i}{t_{i+k} - t_i} N^{k-1}_i(t) + \frac{t_{i+k+1} - t}{t_{i+k+1} - t_{i+1}} N^{k-1}_{i+1}(t), \quad t \in [0, 1],$$

where we assume a fraction with zero denominator to be zero.

It is well-known that the functions in $\{N^1_i, \ldots, N^{n+p}_i\}$ form a basis for the spline space of degree $p$. Moreover, the B-splines possess the following properties

**a1)** Local support property:

$$\text{supp}(N^p_i) = [t_i, t_{i+p+1}], \quad i = 1, \ldots, n + p,$$

**a2)** Vanishing at the boundary:

$$N^p_i(0) = N^p_i(1) = 0, \quad i = 2, \ldots, n + p - 1,$$

**a3)** Nonnegative partition of unity:

$$N^p_i(t) \geq 0, \quad t \in [0, 1], \quad i = 1, \ldots, n + p,$$

$$\sum_{i=1}^{n+p} N^p_i(t) = 1, \quad t \in [0, 1].$$

Now, we turn to the definition of cardinal B-splines.

**Definition 2.2.** A cardinal B-spline of zero degree, denoted by $\phi_0$, is the characteristic function over the interval $[0, 1)$, i.e.,

$$\phi_0(t) := \begin{cases} 1, & t \in [0, 1) \\ 0, & \text{otherwise} \end{cases}.$$

A cardinal B-Spline of degree $q$, $q \in \mathbb{N}$, denoted by $\phi_q$, is defined by convolution as

$$\phi_q(t) = (\phi_{q-1} * \phi_0)(t) = \int_{\mathbb{R}} \phi_{q-1}(t-s)\phi_0(s) \, ds.$$

A cardinal B-Spline of degree $q$ has the following properties

**b1)** Local support property:

$$\text{supp}(\phi_q) = [0, q + 1];$$
b2) Regularity: \( \phi_q \in C^{r-1} \);

b3) Derivative expression: \( \forall t \in [0, q + 1] \) and \( q \geq 1 \), we have

\[
\phi_q'(t) = \phi_{q-1}(t) - \phi_{q-1}(t - 1);
\]

b4) Recursive definition: \( \forall t \in [0, q + 1] \) and \( q \geq 1 \), we have

\[
\phi_q(t) = \frac{t}{q} \phi_{q-1}(t) + \frac{q + 1 - t}{q} \phi_{q-1}(t - 1);
\]

b5) Symmetry: \( \phi_q \) is symmetric on the interval \([0, q + 1]\), i.e.,

\[
\phi_q(t) = \phi_q(q + 1 - t), \quad \forall t \in [0, q + 1];
\]

b6) Inner product: for \( \tau \in \mathbb{R} \), \( q_1, q_2, r_1, r_2 \geq 0 \)

\[
\int_{\mathbb{R}} \phi^{(r_1)}_{q_1}(t) \phi^{(r_2)}_{q_2}(t + \tau) \, dt = (-1)^{r_1} \phi^{(r_1+r_2)}_{q_1+q_2+1}(q_1 + 1 + \tau)
\]

\[
= (-1)^{r_2} \phi^{(r_1+r_2)}_{q_1+q_2+1}(q_2 + 1 - \tau).
\]

Cardinal B-splines are of interest since the so-called central basis functions \( N^p_i \), \( i = p + 1, \ldots, n \), are the uniformly shifted and scaled versions of the cardinal B-splines \( \phi_p \). More precisely, we have

\[
N^p_i(t) = \phi_p(nt - i + p + 1), \quad i = p + 1, \ldots, n,
\]

\[
(N^p_i(t))' = n \phi_p'(nt - i + p + 1), \quad i = p + 1, \ldots, n. \tag{2.2}
\]

We end this subsection by introducing the tensor product B-splines.

**Definition 2.3.** For any pair of d-indices \( n = (n_1, n_2, \ldots, n_d) \) and \( p = (p_1, p_2, \ldots, p_d) \), let us define the tensor product B-splines as follows

\[
N^p_i : [0,1]^d \rightarrow \mathbb{R}, \quad N^p_i(t) = \prod_{j=1}^{d} N^p_{i_j}(t_j), \quad i = 1, \ldots, n + p,
\]

where \( t = (t_1, \ldots, t_d) \in [0,1]^d \), \( 1 = (1, \ldots, 1) \in \mathbb{N}^d \), \( i = (i_1, \ldots, i_d) \in \mathbb{N}^d \).

In the remaining, our attention will be focused on the 2D tensor-product B-spline space

\[
S^{p_1,p_2} := \text{span} \{ N^{p_1}_{i_1}(t_1) N^{p_2}_{i_2}(t_2) \}_{i_1,i_2} \text{ if } i_1 = 1, \ldots, n_1 + p_1 \text{ and } i_2 = 1, \ldots, n_2 + p_2. \tag{2.4}
\]

### 2.2 Unilevel and multilevel Toeplitz matrix-sequences

**Definition 2.4.** A (unilevel) Toeplitz matrix is a real/complex valued \( n \times n \) matrix \( T_n = [t_{ij}]_{i,j=1}^{n} \), where \( t_{ij} = t_{i-j} \), i.e.,

\[
T_n = \begin{bmatrix}
    t_0 & t_{-1} & t_{-2} & \ldots & t_{-(n-1)} \\
    t_1 & t_0 & t_{-1} & \ldots & \\
    t_2 & t_1 & t_0 & \ldots & \\
    \vdots & \ddots & \ddots & \ddots & \\
    t_{n-1} & \ldots & \ldots & t_0 & 
\end{bmatrix}
\]
For any function \( f \in L^1([\pi, \pi]) \), the Fourier coefficients are defined as

\[
\hat{f}_j = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\theta) e^{-ij\theta} \, d\theta,
\]

where the sequence \( \{\hat{f}_j\}_j \) determines uniquely the function \( f \) and vice versa. Therefore, the function \( f \), if it exists, is also uniquely determined by the sequence of the Toeplitz matrices \( \{T_n(f)\}_n \) with

\[
T_n(f) = [\hat{f}_{i-j}]_{i,j=1}^n.
\]

When \( f \in L^1([-\pi, \pi]^d) \), the associated sequence is made of the so-called multilevel Toeplitz matrices, that is matrices which 'at each level' are Toeplitz matrices. For example, a 2-level matrix is a block Toeplitz whose blocks are still Toeplitz. A more general definition of Toeplitz sequences associated to a function is obtained when \( f \) is a matrix-valued function \( f : [-\pi, \pi]^d \rightarrow \mathbb{C}^{s \times s} \) such that all its components \( f_{ij} : [-\pi, \pi]^d \rightarrow \mathbb{C} \), \( i, j = 1, \ldots, s \), belong to \( L^1([-\pi, \pi]^d) \). In this case the associated sequence is made of the so-called multilevel block Toeplitz matrices, that is multilevel Toeplitz matrices whose entries 'at the last level' are \( s \times s \) matrices themselves.

Let \( n := (n_1, \ldots, n_d) \) be a multi-index in \( \mathbb{N}^d \) and set \( N(n) := \prod_{i=1}^d n_i \). The formal definition of \( d \)-level block Toeplitz sequence associated to \( f \) is the following.

**Definition 2.5.** Let \( f : [-\pi, \pi]^d \rightarrow \mathbb{C}^{s \times s} \) such that \( f_{ij} \in L^1([-\pi, \pi]^d) \), \( i, j = 1, \ldots, s \), and let \( \hat{f}_j \) be its Fourier coefficients

\[
\hat{f}_j := \frac{1}{(2\pi)^d} \int_{[-\pi, \pi]^d} f(\theta) e^{-ij\cdot\theta} \, d\theta \in \mathbb{C}^{s \times s},
\]

where \( j = (j_1, \ldots, j_d) \in \mathbb{Z}^d \), \( \theta = (\theta_1, \ldots, \theta_d) \in [-\pi, \pi]^d \), \( \langle j, \theta \rangle = \sum_{r=1}^d j_r \theta_r \) and the integrals in (2.5) are computed componentwise. Then, the \( n \)-th Toeplitz matrix associated with \( f \) is the matrix of order \( sN(n) \) given by

\[
T_n(f) = \left[\hat{f}_{i-j}\right]_{i,j=1}^n = \sum_{|i| < n_1} \cdots \sum_{|j| < n_d} \left[ J_{i,n_1}^{(j_1)} \otimes \cdots \otimes J_{i,n_d}^{(j_d)} \right] \otimes \hat{f}_j,
\]

where \( 1 = (1, \ldots, 1) \in \mathbb{N}^d \), \( i = (i_1, \ldots, i_d) \in \mathbb{N}^d \), \( j = (j_1, \ldots, j_d) \in \mathbb{N}^d \) and \( \otimes \) denotes the (Kronecker) tensor product of matrices. The term \( J_{m,j}^{(k)} \) is the matrix of order \( m \) whose \((i,j)\) entry equals 1 if \( i - j = l \) and zero otherwise. The set \( \{T_n(f)\}_n \) is called the family of \( d \)-level block Toeplitz matrices generated by \( f \), that in turn is referred to as the generating function of \( \{T_n(f)\}_n \).

In the next subsection, in Theorem 2.3 we will see that if \( f \) is a Hermitian matrix-valued function, then \( (f, [-\pi, \pi]^d) \) is also the (spectral) symbol of \( \{T_n(f)\}_n \), in the sense of Definition 2.6 and with \( f \) being the generating function.

### 2.3 Summary of the theory of GLT sequences

In the sequel, we recall the basic properties of the Generalized Locally Toeplitz sequences. More details can be found in the pioneering work [24] by Tilli focused on the spectrum of one-dimensional differential operators and in [23, 22] containing a generalization to multivariate differential operators. As described in [23, 22], a GLT sequence \( \{A_n\}_n \) is a sequence of matrices of increasing size. Before listing some crucial properties of the GLT sequences, we need to introduce the definition of spectral distribution in the sense of the eigenvalues and of the singular values for a generic matrix-sequence \( \{A_n\}_n \).

**Definition 2.6.** Let \( f : G \rightarrow \mathbb{C}^{s \times s} \) be a measurable function, defined on a measurable set \( G \subset \mathbb{R}^l \) with \( l \geq 1 \), \( 0 < m_l(G) < \infty \), where \( m_l \) is the Lebesgue measure. Let \( C_0(K) \) be the set of continuous functions with compact support over \( K \in \{\mathbb{C}, \mathbb{R}^d\} \) and let \( \{A_n\}_n \) be a sequence of matrices with \( \dim(A_n) = d_n \) and \( d_n \rightarrow \infty \), \( n := (n_1, \ldots, n_d) \), as \( n \rightarrow \infty \), i.e., \( n_j \rightarrow \infty \), \( j = 1, \ldots, d \).

- \( \{A_n\}_n \) is distributed as the pair \((f, G)\) in the sense of the eigenvalues, that is

\[
\{A_n\}_n \sim \lambda(f, G),
\]
if the following limit relation holds for all $F \in \mathcal{C}_0(\mathbb{C})$:

$$
\lim_{n \to \infty} \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) = \frac{1}{m_1(G)} \int_G \frac{\sum_{i=1}^{s} F(\lambda_i(f(t)))}{s} dt,
$$

(2.6)

where $\lambda_j(A_n)$, $j = 1, \ldots, d_n$ are the eigenvalues of $A_n$ and $\lambda_i(f)$, $i = 1, \ldots, s$ are the eigenvalues of $f$. In this case, we say that $f$ is the (spectral) symbol of the matrix-sequence $\{A_n\}_n$.

- $\{A_n\}_n$ is distributed as the pair $(f, G)$ in the sense of the singular values, that is

$$
\{A_n\}_n \sim_\sigma (f, G),
$$

if the following limit relation holds for all $F \in \mathcal{C}_0(\mathbb{R}_0^+)$:

$$
\lim_{n \to \infty} \frac{1}{d_n} \sum_{j=1}^{d_n} F(\sigma_j(A_n)) = \frac{1}{m_1(G)} \int_G \frac{\sum_{i=1}^{s} F(\sigma_i(f(t)))}{s} dt,
$$

(2.7)

where $\sigma_j(A_n)$, $j = 1, \ldots, d_n$ are the singular values of $A_n$ and $\sigma_i(f)$, $i = 1, \ldots, s$ are the singular values of $f$. In this case, we say that $f$ is the singular value symbol of the matrix-sequence $\{A_n\}_n$.

Remark 2.1. If $f$ is smooth enough, an informal interpretation of the limit relation (2.6) (resp. (2.7)) is that when the matrix-size of $A_n$ is sufficiently large, then $d_n/s$ eigenvalues (resp. singular values) of $A_n$ can be approximated by a sampling of $\lambda_1(f)$ (resp. $\sigma_1(f)$) on a uniform equispaced grid of the domain $G$, and so on until the last $d_n/s$ eigenvalues (resp. singular values) can be approximated by an equispaced sampling of $\lambda_s(f)$ (resp. $\sigma_s(f)$) in the domain.

In the following, we recall two well-known results on the spectral distribution of Toeplitz sequences. If $f$ is a real-valued function, the following theorem due to Szegö holds.

Theorem 2.2 ([13]). Let $f \in L^1([–\pi, \pi]^d)$ be a real-valued function. Then, $\{T_n(f)\}_n \sim_\lambda (f, [–\pi, \pi]^d)$.

In the case where $f$ is a Hermitian matrix-valued function, the previous theorem can be extended as follows:

Theorem 2.3 ([25]). Let $f : [–\pi, \pi]^d \to \mathbb{C}^{s \times s}$ be a Hermitian matrix-valued function. Then, $\{T_n(f)\}_n \sim_\lambda (f, [–\pi, \pi]^d)$.

We are now ready to provide more details on the GLT sequences. Each GLT sequence is associated to a complex-valued Lebesgue-measurable function $\kappa$, which is known as the symbol of the sequence $\{A_n\}_n$. In this case, we note $\{A_n\}_n \sim_{\text{GLT}} \kappa$. The domain of definition $G$ of the symbol is taken as $[0, 1]^d \times [–\pi, \pi]^d$ while a point in $G$ is denoted by $(x, \theta)$, where $x = (x_1, \ldots, x_d)$ are the physical variables and $\theta = (\theta_1, \ldots, \theta_d)$ are the Fourier variables.

We recall the following properties of a GLT sequence $\{A_n\}_n$:

GLT1 Let $\{A_n\}_n \sim_{\text{GLT}} \kappa$ with $\kappa : G \to \mathbb{C}$, $G = [0, 1]^d \times [–\pi, \pi]^d$, then $\{A_n\}_n \sim_\sigma (\kappa, G)$. If the matrices $A_n$ are definitely Hermitian, that is $A_n - A_n^d$ is ‘small enough’ (see Theorem 3.4 in [12]), then it holds also $\{A_n\}_n \sim_\lambda (\kappa, G)$.

GLT2 The set of GLT sequences form a $\ast$-algebra, i.e., it is closed under linear combinations, products, inversion, conjugation: hence, the sequence obtained via algebraic operations on a finite set of input GLT sequences is still a GLT sequence and its symbol is obtained by following the same algebraic manipulations on the corresponding symbols of the input GLT sequences. In symbols, let $\{A_n\}_n \sim_{\text{GLT}} \kappa_1$ and $\{B_n\}_n \sim_{\text{GLT}} \kappa_2$, then

- $\{\alpha A_n + \beta B_n\}_n \sim_{\text{GLT}} \alpha \kappa_1 + \beta \kappa_2$, $\alpha, \beta \in \mathbb{C}$;
- $\{A_n B_n\}_n \sim_{\text{GLT}} \kappa_1 \kappa_2$;
- if $\kappa_1$ vanishes, at most, in a set of zero Lebesgue measure, then $\{A_n^{-1}\}_n \sim_{\text{GLT}} \kappa_1^{-1}$;
- $\{A_n^*\}_n \sim_{\text{GLT}} \kappa_1$.

GLT 3 Any sequence of Toeplitz matrices $\{T_n(f)\}_n$ generated by a function $f \in L^1([–\pi, \pi]^d)$ is a GLT sequence with symbol $\kappa(x, \theta) = f(\theta)$. 

6
Any sequence of diagonal matrices \(\{D_n(a)\}_n\) whose diagonal is made of the evaluations of a Riemann-integrable function \(a : [0, 1]^d \to \mathbb{C}\) over a uniform grid is a GLT sequence with symbol \(\kappa(x, \theta) = a(x)\).

Every sequence which is distributed as the constant zero in the singular value sense is a GLT sequence with symbol 0 and vice versa, i.e., \(\{A_n\}_n \sim_0 0 \iff \{A_n\}_n \sim_{GLT} 0\).

We end this subsection introducing the notion of zero-distributed matrix-sequences and giving a characterization for them.

**Definition 2.7.** Let \(\{A_n\}_n\) be a sequence of matrices with \(\dim(A_n) = d_n\) and \(d_n \to \infty\) as \(n \to \infty\). We say that \(\{A_n\}_n\) is a zero-distributed matrix-sequence if \(\{A_n\}_n \sim_0 0\).

**Theorem 2.4** ([8]). The matrix-sequence \(\{A_n\}_n\) is zero-distributed if and only if for all \(n \in \mathbb{N}^d\)

\[
A_n = R_n + N_n,
\]

where

\[
\lim_{n \to \infty} \frac{\text{rank}(R_n)}{d_n} = \lim_{n \to \infty} \|N_n\| = 0.
\]

Here \(\|\cdot\|\) is the spectral norm.

### 2.4 IgA mass and stiffness matrices

In the context of IgA discretization of elliptic problems, we often deal with the following mass and stiffness matrices

\[
M_n^p = \left[ \int_0^1 N_{i_1}^p(t) N_{j_1}^p(t) \, dt \right]_{i_1,j_1=1}^{n+p},
\]

\[
S_n^p = \left[ \int_0^1 (N_{i_1}^p(t))^\prime \, (N_{j_1}^p(t))^\prime \, dt \right]_{i_1,j_1=1}^{n+p}.
\]

We know that the matrices \(M_n^p\) and \(S_n^p\) are Symmetric Positive Definite (SPD) matrices (see e.g. [7]). Furthermore, using the results of Subsection 2.1, these matrices can be expressed as

\[
(M_n^p)_{i_1,j_1} = \frac{1}{n} \phi_{2p+1}(p + 1 - (i_1 - j_1)),
\]

\[
(S_n^p)_{i_1,j_1} = -n\phi''_{2p+1}(p + 1 - (i_1 - j_1)),
\]

up to a low-rank perturbation (see [8, 9]), that is, they are low-rank perturbations of Toeplitz matrices. Thanks to the results in Subsection 2.3, the following theorems on the symbol of the sequences of mass and stiffness matrices in (2.8)-(2.9) hold.

**Theorem 2.5.** \(\{nM_n^p\}_n \sim_{GLT} m_p\) and \(\{nS_n^p\}_n \sim_{\sigma,\lambda} (m_p, [-\pi, \pi])\), where the symbol \(m_p\) is given by

\[
m_p(x, \theta) := m_p(\theta) = \phi_{2p+1}(p + 1) + 2 \sum_{k=1}^{p} \phi_{2p+1}(p + 1 - k) \cos(k\theta).
\]

**Theorem 2.6.** \(\{\frac{1}{n}S_n^p\}_n \sim_{GLT} s_p\) and \(\{\frac{1}{n}S_n^p\}_n \sim_{\sigma,\lambda} (s_p, [-\pi, \pi])\), where the symbol \(s_p\) is given by

\[
s_p(x, \theta) := s_p(\theta) = -\phi''_{2p+1}(p + 1) - 2 \sum_{k=1}^{p} \phi_{2p+1}(p + 1 - k) \cos(k\theta).
\]

The symbols \(m_p(\theta)\) and \(s_p(\theta)\) satisfy the following properties for all \(p \geq 1\) and \(\theta \in [-\pi, \pi]\) (see [7, 4]):

**c1)** \(s_p(\theta) = m_{p-1}(\theta)(2 - 2\cos(\theta))\);

**c2)** Let \(M_{s_p}\) be \(\max_{[0, \pi]} s_p(\theta)\). Then

\[
\frac{s_p(\pi)}{M_{s_p}} \leq 2^{2-p},
\]

which means that \(\frac{s_p(\pi)}{M_{s_p}}\) decreases exponentially to zero as \(p \to \infty\);
where

\[ S \]

More precisely,

\[ S \]

Remark 2.7. As a result of the previous properties, the function \( s_p(\theta) \) has a unique zero of order 2 at 0 (like the function \( 2 - 2\cos(\theta) \)). On the other hand, from a numerical point of view, we can say that, for large \( p \), the normalized symbol \( \frac{s_p(\theta)}{M_{sp}} \) has also an exponential numerical zero at \( \theta = \pi \).

3 IgA discretization of curl-curl operator

In [2], the construction of a discrete De Rham sequence using B-Splines is established, which provides the following commutative diagram:

\[
\begin{array}{cccccc}
H^1(\Omega) & \xrightarrow{\nabla} & H(\text{curl}, \Omega) & \xrightarrow{\nabla \times} & H(\text{div}, \Omega) & \xrightarrow{\nabla} & L^2(\Omega) \\
\Pi_h^{\text{grad}} & & \Pi_h^{\text{curl}} & & \Pi_h^{\text{div}} & & \Pi_h^{L^2} \\
V_h(\text{grad}, \Omega) & \xrightarrow{\nabla} & V_h(\text{curl}, \Omega) & \xrightarrow{\nabla \times} & V_h(\text{div}, \Omega) & \xrightarrow{\nabla} & V_h(L^2, \Omega)
\end{array}
\]

In the 2D case, the previous diagram is reduced into 2 diagrams. For this work, we are concerned by the following commuting diagram:

\[
\begin{array}{cccccc}
H^1(\Omega) & \xrightarrow{\nabla} & H(\text{curl}, \Omega) & \xrightarrow{\nabla \times} & L^2(\Omega) \\
\Pi_h^{\text{grad}} & & \Pi_h^{\text{curl}} & & \Pi_h^{L^2} \\
V_h(\text{grad}, \Omega) & \xrightarrow{\nabla} & V_h(\text{curl}, \Omega) & \xrightarrow{\nabla \times} & V_h(L^2, \Omega)
\end{array}
\]

where

\[ V_h(\text{grad}, \Omega) = S^{p-p}, \quad V_h(\text{curl}, \Omega) = \left( S^{p-1,p} \right), \quad \text{and} \quad V_h(L^2, \Omega) = S^{p-1,p-1}. \]

More precisely,

\[ V_h(\text{curl}, \Omega) = S^{p-1,p} \times S^{p-1,p} = \text{span}\{\psi^1_{i_1,i_2}, \psi^2_{j_1,j_2}\}_{i_1,i_2,j_1,j_2}, \]

where \( S^{p-1,p} \) and \( S^{p-1,p} \) are defined as in (2.4) namely

\[
S^{p-1,p} := \text{span}\left\{ N_{i_1}^{p-1}(t_1)N_{i_2}^{p}(t_2) \right\}_{i_1,i_2}, \quad i_1 = 1, \ldots, n_1 + p - 1, \quad i_2 = 1, \ldots, n_2 + p,
\]

\[
S^{p-1,p} := \text{span}\left\{ N_{j_1}^{p}(t_1)N_{j_2}^{p-1}(t_2) \right\}_{j_1,j_2}, \quad j_1 = 1, \ldots, n_1 + p, \quad j_2 = 1, \ldots, n_2 + p - 1,
\]

\[
\psi^1_{i_1,i_2} = \begin{bmatrix} N_{i_1}^{p-1}(t_1)N_{i_2}^{p}(t_2) \\ 0 \end{bmatrix}, \quad \psi^2_{j_1,j_2} = \begin{bmatrix} 0 \\ N_{j_1}^{p}(t_1)N_{j_2}^{p-1}(t_2) \end{bmatrix}.
\]

Problem (1.1) at the discrete level then reads as

\[
\mathbf{u} \in V_h(\text{curl}, \Omega) : \quad (\nabla \times \mathbf{u}, \nabla \times \mathbf{v}) + \mu (\mathbf{u}, \mathbf{v}) = (f, \mathbf{v}), \quad \forall \mathbf{v} \in V_h(\text{curl}, \Omega), \quad (3.1)
\]

Remark 3.1. Boundary contributions are considered to be included in the right hand side term \( f \). Therefore, no essential boundary conditions are imposed in the construction of the Finite Elements space, and all the degrees of freedom are taken into account here. Moreover, weak boundary conditions such as the Nitsche’s method, are not considered in the following paper and may be covered in a future work.

Using the expansion

\[
\mathbf{u} = \begin{bmatrix} \sum_{i_1=1}^{n_1+p} \sum_{i_2=1}^{n_2+p} u^1_{i_1,i_2} N_{i_1}^{p-1}(t_1)N_{i_2}^{p}(t_2) \\ \sum_{j_1=1}^{n_1+p} \sum_{j_2=1}^{n_2+p} u^2_{j_1,j_2} N_{j_1}^{p}(t_1)N_{j_2}^{p-1}(t_2) \end{bmatrix},
\]
and choosing \( \mathbf{v} = \psi_{i_1, i_2}' \), we obtain

\[
(\nabla \times \mathbf{u}, \nabla \times \psi_{i_1, i_2}^1) =
\]

\[
- \sum_{j_1 = 1}^{n_1 + p} \sum_{j_2 = 1}^{n_2 + p - 1} u_{j_1, j_2}^2 \int_\Omega \left( N_{j_1}^p (t_1) \right) \left( N_{j_2}^p (t_2) \right) \left( N_{j_1}^{p-1} (t_1) \right) \left( N_{j_2}^{p-1} (t_2) \right) \, dt_1 \, dt_2
\]

\[
+ \sum_{i_1 = 1}^{n_1 + p - 1} \sum_{i_2 = 1}^{n_2 + p} u_{i_1, i_2}^1 \int_\Omega \left( N_{i_1}^p (t_1) \right) \left( N_{i_2}^p (t_2) \right) \left( N_{i_1}^{p-1} (t_1) \right) \left( N_{i_2}^{p-1} (t_2) \right) \, dt_1 \, dt_2,
\]

\[
= - \sum_{j_1 = 1}^{n_1 + p} \sum_{j_2 = 1}^{n_2 + p - 1} u_{j_1, j_2}^2 \left( A_{j_1, j_2}^p \otimes A_{j_1, j_2}^p \right)_{\sim, \sim, \sim, \sim},
\]

\[
+ \sum_{i_1 = 1}^{n_1 + p - 1} \sum_{i_2 = 1}^{n_2 + p} u_{i_1, i_2}^1 \left( M_{i_1, i_2}^{p-1} \otimes S_{i_1, i_2}^p \right)_{\sim, \sim, \sim, \sim}, \tag{3.2}
\]

where \( M_{n_1}^{p-1} \) and \( S_{n_2}^p \) are defined as in (2.8) and (2.9), i.e.,

\[
(M_{n_1}^{p-1})_{i_1, i_1} = \int_0^1 N_{i_1}^{p-1} (t_1) N_{i_1}^{p-1} (t_1) \, dt_1, \quad \sim, \sim, \sim, \sim,
\]

\[
(S_{n_2}^p)_{i_2, i_2} = \int_0^1 (N_{i_2}^p (t_2))' \left( N_{i_2}^p (t_2) \right)' \, dt_2, \quad \sim, \sim, \sim, \sim,
\]

while

\[
(A_{n_1}^p)_{i_1, j_1} = \int_0^1 N_{i_1}^{p-1} (t_1) \left( N_{j_1}^p (t_1) \right)' \, dt_1, \quad \sim, \sim, \sim, \sim,
\]

\[
(A_{n_2}^p)_{i_2, j_2} = \int_0^1 N_{i_2}^{p-1} (t_2) \left( N_{j_2}^p (t_2) \right)' \, dt_2, \quad \sim, \sim, \sim, \sim.
\]

Equation (3.2) can be expressed in compact form as follows

\[
M_{n_1}^{p-1} \otimes S_{n_2}^p u_1^1 - A_{n_1}^p \otimes A_{n_2}^p u_2^2. \tag{3.3}
\]

On the other hand, if we choose \( \mathbf{v} = \psi_{j_1, j_2}' \), then we obtain

\[
(\nabla \times \mathbf{u}, \nabla \times \psi_{j_1, j_2}^2) =
\]

\[
- \sum_{j_1 = 1}^{n_1 + p} \sum_{j_2 = 1}^{n_2 + p - 1} u_{j_1, j_2}^2 \int_\Omega \left( N_{j_1}^p (t_1) \right) \left( N_{j_2}^p (t_2) \right) \left( N_{j_1}^{p-1} (t_1) \right) \left( N_{j_2}^{p-1} (t_2) \right) \, dt_1 \, dt_2
\]

\[
+ \sum_{i_1 = 1}^{n_1 + p - 1} \sum_{i_2 = 1}^{n_2 + p} u_{i_1, i_2}^1 \int_\Omega \left( N_{i_1}^p (t_1) \right) \left( N_{i_2}^p (t_2) \right) \left( N_{i_1}^{p-1} (t_1) \right) \left( N_{i_2}^{p-1} (t_2) \right) \, dt_1 \, dt_2,
\]

\[
= \sum_{j_1 = 1}^{n_1 + p} \sum_{j_2 = 1}^{n_2 + p - 1} u_{j_1, j_2}^2 \left( S_{n_1}^p \otimes M_{n_2}^{p-1} \right)_{\sim, \sim, \sim, \sim},
\]

\[
- \sum_{i_1 = 1}^{n_1 + p - 1} \sum_{i_2 = 1}^{n_2 + p} u_{i_1, i_2}^1 \left( B_{n_1}^p \otimes B_{n_2}^p \right)_{\sim, \sim, \sim, \sim} \tag{3.4}
\]

where \( M_{n_2}^{p-1} \) and \( S_{n_1}^p \) are defined as in (2.8) and (2.9), i.e.,

\[
(M_{n_2}^{p-1})_{j_2, j_2} = \int_0^1 N_{j_2}^{p-1} (t_2) N_{j_2}^{p-1} (t_2) \, dt_2, \quad \sim, \sim, \sim, \sim,
\]

\[
(S_{n_1}^p)_{j_1, j_1} = \int_0^1 (N_{j_1}^p (t_1))' \left( N_{j_1}^p (t_1) \right)' \, dt_1, \quad \sim, \sim, \sim, \sim.
\]
while

\[
B_{n_1}^p = (A_{n_1}^p)^T, \\
B_{n_2}^p = (A_{n_2}^p)^T.
\]

Equation (3.4) can be rewritten in compact form as follows

\[
S_{n_1}^p \otimes M_{n_2}^{p-1} u^2 - (A_{n_1}^p \otimes A_{n_2}^p)^T u^1.
\]  

(3.5)

Putting together equations (3.3) and (3.5), we obtain the following two-by-two matrix

\[
\mathcal{A}_n = \begin{bmatrix}
M_{n_1}^{p-1} \otimes S_{n_2}^p & -A_{n_1}^p \otimes A_{n_2}^p \\
-(A_{n_1}^p \otimes A_{n_2}^p)^T & S_{n_1}^p \otimes M_{n_2}^{p-1}
\end{bmatrix}.
\]

(3.6)

Such a matrix is the result of the IgA discretization of the curl-curl operator \((\nabla \times \cdot, \nabla \times \cdot)\) appearing in problem (1.1). In order to complete the operator in the left-hand side of (1.1) by adding the zero-order term \(\mu (\cdot, \cdot)\), we obtain the following two-by-two coefficient matrix for problem (3.1)

\[
\mathcal{A}_n^\mu = \mathcal{A}_n + \mu \begin{bmatrix}
M_{n_1}^{p-1} \otimes M_{n_2}^p & 0 \\
0 & M_{n_1}^p \otimes M_{n_2}^{p-1}
\end{bmatrix},
\]

(3.7)

where \(0\) is the null matrix of size \((n_1+p-1)(n_2+p) \times (n_1+p)(n_2+p-1)\). Note that according to our notation, \(\mathcal{A}_n^0 = \mathcal{A}_n\).

**Remark 3.2.** In the general case in which \(n_1 \neq n_2\) the blocks of \(\mathcal{A}_n^\mu\) have different sizes and the matrices on the antidiagonal are rectangular. On the contrary, if \(n_1 = n_2\) all blocks are square matrices and have the same size. In spite of this, \(\mathcal{A}_{n_1}^p\) and \(\mathcal{A}_{n_2}^p\) are always rectangular matrices of size \((n_1+p-1) \times (n_1+p)\), \((n_2+p) \times (n_2+p-1)\), respectively.

## 4 Spectral analysis of the matrices \(\mathcal{A}_n\) and \(\mathcal{A}_n^\mu\)

The main aim of this section is to provide a spectral analysis of the matrix-sequences \(\left\{ \mathcal{A}_n \right\}_n\), \(\left\{ \mathcal{A}_n^\mu \right\}_n\) with \(\mathcal{A}_n\) and \(\mathcal{A}_n^\mu\) defined as (3.6) and (3.7), respectively. Because of the rectangular nature of the matrices on the antidiagonal of \(\mathcal{A}_n\), to compute the symbol of the matrix-sequence \(\left\{ \mathcal{A}_n \right\}_n\), we need to look at a bigger matrix \(\tilde{\mathcal{A}}_n\), whose blocks are square matrices with same size, and then to use a sort of interlacing theorem for symbols (Theorem 4.3), for recovering the spectral information on the original matrix-sequence. Let us build the matrix \(\tilde{\mathcal{A}}_n\) as follows

\[
\tilde{\mathcal{A}}_n = \begin{bmatrix}
\tilde{\mathcal{A}}_{n_1}^{(1,1)} & \tilde{\mathcal{A}}_{n_1}^{(1,2)} \\
\tilde{\mathcal{A}}_{n_1}^{(2,1)} & \tilde{\mathcal{A}}_{n_1}^{(2,2)}
\end{bmatrix} = \begin{bmatrix}
\tilde{M}_{n_1}^{p-1} \otimes S_{n_2}^p & -\tilde{A}_{n_1}^p \otimes \tilde{A}_{n_2}^p \\
-(\tilde{A}_{n_1}^p \otimes \tilde{A}_{n_2}^p)^T & S_{n_1}^p \otimes \tilde{M}_{n_2}^{p-1}
\end{bmatrix},
\]

where

\[
(\tilde{M}_{n_1}^{p-1})_{ij} = \int_0^1 N_i^{p-1}(t_1) N_j^{p-1}(t_1) dt_1, \quad i, j = 1, \ldots, n_1 + p,
\]

\[
(\tilde{M}_{n_2}^{p-1})_{hk} = \int_0^1 N_k^{p-1}(t_2) N_h^{p-1}(t_2) dt_2, \quad h, k = 1, \ldots, n_2 + p,
\]

\[
(\tilde{A}_{n_1}^p)_{ij} = \int_0^1 N_i^{p-1}(t_1) \left(N_j^p(t_1)\right)' dt_1, \quad i, j = 1, \ldots, n_1 + p,
\]

\[
(\tilde{A}_{n_2}^p)_{hk} = \int_0^1 N_k^{p-1}(t_2) \left(N_h^p(t_2)\right)' dt_2, \quad h, k = 1, \ldots, n_2 + p.
\]

**Remark 4.1.** The new matrices assume the construction of additional B-Splines. In order to keep the same Spline space, the new spline of degree \(p - 1\) is associated to the knots \([t_{p+n+1}, \ldots, t_{2p+n+1}]\) and therefore it is identically equal to zero. Notice, that any additional B-Spline is admissible since our study only takes into account the internal knots.

More precisely, our strategy is the following:
• compute the symbol of \( \{ \tilde{A}_n \}_n \) by computing the symbol of each block \( \{ \tilde{A}^{(i,j)}_n \}_n \), \( i, j = 1, 2 \);
• use the knowledge of the symbol of \( \{ \tilde{A}_n \}_n \) to retrieve the symbol of the original matrix-sequence \( \{ A_n \}_n \) and then of \( \{ A'_n \}_n \).

Both steps require Theorem 4.3, which in turn needs Lemma 4.2. These two tools are of general interest and therefore a specific subsection is dedicated to them.

4.1 Distribution tools: an extradimensional approach

In this subsection we first extend the set of possible test functions (following an idea in [21]) and then connect the distribution of a sequence of matrices and of specific subsequences, constructed using principal submatrices with given constraints on the dimension (see Theorem 4.3). The idea is to overcome the difficulty encountered in the distribution of a sequence of matrices and of specific subsequences, constructed using principal submatrices.

In this subsection we first extend the set of possible test functions (following an idea in [21]) and then connect the distribution of a sequence of matrices and of specific subsequences, constructed using principal submatrices with given constraints on the dimension (see Theorem 4.3). The idea is to overcome the difficulty encountered in the distribution of a sequence of matrices and of specific subsequences, constructed using principal submatrices.

Lemma 4.2. If \( \{ A_n \}_n \sim \lambda (f, G) \) with \( A_n \) Hermitian matrix such that \( \dim(\tilde{A}_n) = d_n, \ d_n \to \infty \) as \( n \to \infty \) and \( f \) and \( G \) as in Definition 2.6, then for every \( F \) continuous and bounded on \( \mathbb{R} \)

\[
\lim_{n \to \infty} \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) = \frac{1}{m_1(G)} \int_{G} \sum_{i=1}^{n} F(\lambda_i(f(t))) \frac{dt}{s} =: \phi(F).
\]

Proof. We want to prove that

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) - \phi(F) \right| \to 0 \quad \text{as} \quad n \to \infty.
\]

Let us rewrite relation (4.1) as follows

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) - \phi(F) \right| \leq \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) - \frac{1}{d_n} \sum_{j=1}^{d_n} F_m(\lambda_j(A_n)) + \frac{1}{d_n} \sum_{j=1}^{d_n} F_m(\lambda_j(A_n)) - \phi(F_m) + |\phi(F_m) - \phi(F)|
\]

and let us focus our attention on the first term on the right-hand of (4.2). Using 3. and the hypothesis \( \{ A_n \}_n \sim \lambda (f, G) \) we obtain

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) - \frac{1}{d_n} \sum_{j=1}^{d_n} F_m(\lambda_j(A_n)) \right| \leq \| F - F_m \|_{\infty} \frac{\#(j : \lambda_j(A_n) \notin [-m, m])}{d_n} \leq 2\| F \|_{\infty} r(m)
\]

11
with \( r(m) \to 0 \) as \( m \to \infty \). Thanks to item 1. and using again the hypothesis, we deduce that the second term on the right-hand of (4.2) tends to zero for every fixed \( m \) and for \( n \to \infty \). Moreover, because of 2. and 3. we can apply the dominated convergence theorem to conclude that the third term on the right-hand of (4.2) tends to zero for \( m \to \infty \), independently of \( n \). Therefore,

\[
\lim_{n \to \infty} \sup \left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) \right| 
\leq 2\|F\|_{\infty} r(m) + |\phi(F_m) - \phi(F)|
\]

and then passing to the limit as \( m \to \infty \) we obtain the thesis.

We note that Lemma 4.2 can be seen as an extension to a generic sequence of Hermitian matrices of the results for Toeplitz sequences contained in [21]: in that paper for \( f \in L^q \) it is shown that the test functions \( F \) have to be continuous and with a growth bound indicated by the relation \( |F(z)| \leq c|z|^q \) for some constant \( c \) with \( q \geq 1 \). The argument shown in Lemma 4.2 shows that a generalization is possible also for \( q = 0 \) which is exactly the one considered in the previous lemma, by identifying the set of measurable functions with \( L^0 \).

Now, we will use it to prove the following theorem.

**Theorem 4.3.** Let \( \{\tilde{A}_n\}_n \) be a sequence of Hermitian matrices with \( \dim(\tilde{A}_n) = d_n, d_n \to \infty \) as \( n \to \infty \) and let \( f \) and \( G \) as in Definition 2.6. Define \( A_n = P_n^H \tilde{A}_n P_n \) with \( P_n \in \mathbb{C}^{d_n \times d_n}, d_n < d_n, \) and \( P_n^H P_n = I_{d_n} \). If

\[
\lim_{n \to \infty} \frac{\delta_n}{d_n} = 1,
\]

then

\[
\{\tilde{A}_n\}_n \sim_\lambda (f,G) \iff \{A_n\}_n \sim_\lambda (f,G).
\]

**Proof.** Throughout the proof of this theorem, we assume the eigenvalues of \( \tilde{A}_n \) and \( A_n \) to be ordered as follows

\[
\lambda_1(\tilde{A}_n) \geq \ldots \geq \lambda_{d_n}(\tilde{A}_n), \quad \lambda_1(A_n) \geq \ldots \geq \lambda_{d_n}(A_n).
\]

Let us observe that the thesis can be rewritten as follows: for every \( F \in C_0(\mathbb{R}) \)

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right|
\]

tends to 0 as \( n \to 0 \). It easy to convince the reader that \( \forall F \in C_0(\mathbb{R}) \) and \( \forall \epsilon > 0 \) there exists \( F_\epsilon \in C_0^1(\mathbb{R}) \) (\( C_0^1(\mathbb{R}) \) is the space of functions in \( C^1(\mathbb{R}) \) with compact support) such that \( \|F - F_\epsilon\|_{\infty} < \epsilon \). This implies that

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right|
\leq 2\epsilon + \left| \frac{1}{d_n} \sum_{j=1}^{d_n} F_\epsilon(\lambda_j(\tilde{A}_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F_\epsilon(\lambda_j(A_n)) \right|
\]

Moreover, \( F_\epsilon \in C_0^1(\mathbb{R}) \) can be expressed as the difference between two nonnegative, non-decreasing, bounded functions:

\[
F_\epsilon = F_\epsilon^+ - F_\epsilon^-,
\]
Thanks to the Cauchy Interlacing theorem (see e.g. [1]), we know that

From the monotonicity of

Putting together (4.6) and (4.7), we can conclude that the first term in the right-hand side of (4.5) can be

\[ \delta_n \to 0 \text{ as } n \to \infty \]

In order to give an upper bound for the first term in the right-hand side of (4.5) with a quantity which tends to 0 as \( n \to \infty \), we first observe that, using the hypothesis \( \{A_n\}_n \sim \chi (f, G) \) and applying Lemma 4.2, we find

\[ \lim_{n \to \infty} \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(A_n)) = \phi(F). \quad (4.6) \]

Moreover, from hypothesis (4.3), we deduce \( \delta_n = d_n + o(d_n) \) and then

\[ \lim_{n \to \infty} \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) = \phi(F). \quad (4.7) \]

Putting together (4.6) and (4.7), we can conclude that the first term in the right-hand side of (4.5) can be bounded from above by a quantity which tends to 0 as \( n \to \infty \). Concerning the second term in the right-hand side of (4.5), we start by defining

\[
\begin{align*}
    a_n &= \sum_{j=1}^{\delta_n} F(\lambda_j(\tilde{A}_n)), \\
    b_n &= \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)), \\
    c_n &= \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)).
\end{align*}
\]

Thanks to the Cauchy Interlacing theorem (see e.g. [1]), we know that

\[ \lambda_j(\tilde{A}_n) \geq \lambda_j(A_n) \geq \lambda_j + \delta_n(A_n), \quad j = 1, \ldots, \delta_n. \]

From the monotonicity of \( F \) and from the Cauchy Interlacing theorem, we find

\[ a_n \geq b_n \geq c_n. \]

Both \( a_n/\delta_n \) and \( c_n/\delta_n \) tend to the limit given in (4.7). This implies that \( b_n/\delta_n \) converges to the same limit and the necessary condition is proved.

To prove the sufficient condition, we start from the quantity (4.4), by taking into account the following inequality

\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right| \leq \left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right| + \left| \frac{1}{d_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) - \frac{1}{\delta_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right| \quad (4.8)
\]
In order to bound from above the first term in the right-hand side of (4.8), we use the Cauchy Interlacing theorem, by obtaining
\[
\frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) \geq \frac{1}{d_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \geq \frac{1}{d_n} \sum_{j=1}^{\delta_n} F(\lambda_{j+d_n-\delta_n}(\tilde{A}_n)).
\]
Consequently,
\[
\left| \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{d_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n)) \right| = \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{d_n} \sum_{j=1}^{\delta_n} F(\lambda_j(A_n))
\]
\[
\leq \frac{1}{d_n} \sum_{j=1}^{d_n} F(\lambda_j(\tilde{A}_n)) - \frac{1}{d_n} \sum_{j=1+d_n-\delta_n}^{d_n} F(\lambda_j(\tilde{A}_n))
\]
\[
= \frac{1}{d_n} \sum_{j=1}^{d_n-\delta_n} F(\lambda_j(\tilde{A}_n)) \leq \frac{1}{d_n} \sum_{j=1}^{d_n-\delta_n} \|F\|_X
\]
\[
= \frac{d_n - \delta_n}{d_n} \|F\|_X.
\]
Thanks to hypothesis (4.3), we can conclude that the first term in the right-hand side of (4.8) can be bounded from above by a quantity which tends to 0 as \(n \to \infty\). As a consequence of hypothesis \(\{A_n\}_n \sim \lambda(f,G)\), of the fact that \(d_n - \delta_n = o(d_n)\), and of Lemma 4.2, the same is true also for second term in the right-hand side of (4.8) and the proof of the theorem is complete. \(\square\)

We end this subsection by observing that Theorem 4.3 can be extended to sequences of non-Hermitian matrices and related sequences of principal submatrices, when replacing the eigenvalue distribution with the singular value one. See the following corollary and the given proof sketch.

**Corollary 4.4.** Let \(\{\tilde{A}_n\}_n\) be a sequence of matrices with \(\text{dim}(\tilde{A}_n) = d_n\), \(d_n \to \infty\) as \(n \to \infty\) and let \(f\) and \(G\) as in Definition 2.6. Define \(A_n = \mathcal{P}_n^{\tilde{A}_n} \mathcal{P}_n\), with \(\mathcal{P}_n \in \mathbb{C}^{d_n \times d_n}\), \(\delta_n < d_n\), and \(\mathcal{P}_n^{\tilde{A}_n} \mathcal{P}_n = I_{\delta_n}\). If relation (4.3) holds, then
\[
\{\tilde{A}_n\}_n \sim_{\sigma} (f,G) \iff \{A_n\}_n \sim_{\sigma} (f,G).
\]

**Proof.** For any matrix \(\tilde{A}_n\) with \(\text{dim}(\tilde{A}_n) = d_n\) and any principal submatrix \(A_n = \mathcal{P}_n^{\tilde{A}_n} \mathcal{P}_n\) of \(\tilde{A}_n\) with \(\text{dim}(A_n) = \delta_n < d_n\) satisfying (4.3) let us consider the following block matrices of double size
\[
\tilde{B}_n = \begin{bmatrix} 0 & \tilde{A}_n^H \\ \tilde{A}_n & 0 \end{bmatrix} \in \mathbb{C}^{2d_n \times 2d_n}, \quad B_n = \begin{bmatrix} 0 & A_n^H \\ A_n & 0 \end{bmatrix} \in \mathbb{C}^{2\delta_n \times 2\delta_n}.
\]
By construction, both \(\tilde{B}_n\) and \(B_n\) are Hermitian matrices. Moreover, \(B_n\) is a principal submatrix of \(\tilde{B}_n\) such that relation (4.3) holds. Indeed, if we define
\[
\mathcal{P}_n^{[2]} = \begin{bmatrix} \mathcal{P}_n & 0 \\ 0 & \mathcal{P}_n \end{bmatrix} \in \mathbb{C}^{2d_n \times 2d_n},
\]
then \(B_n = (\mathcal{P}_n^{[2]})^H \tilde{B}_n \mathcal{P}_n^{[2]}\) and \((\mathcal{P}_n^{[2]})^H \mathcal{P}_n^{[2]} = I_{2\delta_n}\). Therefore, thanks to Theorem 4.3 we have that
\[
\{\tilde{B}_n\}_n \sim_{\lambda} (f,G) \iff \{B_n\}_n \sim_{\lambda} (f,G).
\]
On the other hand, it is well known that the eigenvalues of \(\tilde{B}_n\) are given by
\[
\lambda_j(\tilde{B}_n) = \sigma_j(\tilde{A}_n),
\]
\[
\lambda_{d_n+j}(\tilde{B}_n) = -\sigma_{d_n-j+1}(\tilde{A}_n), \quad j = 1, \ldots, d_n,
\]
with both \(\lambda_j(\tilde{B}_n)\) and \(\sigma_j(\tilde{A}_n)\) arranged in non-increasing order. Similarly, the eigenvalues of \(B_n\) are given by
\[
\lambda_j(B_n) = \sigma_j(A_n),
\]
\[
\lambda_{\delta_n+j}(B_n) = -\sigma_{\delta_n-j+1}(A_n), \quad j = 1, \ldots, \delta_n.
\]
with both $\lambda_j(B_n)$ and $\sigma_j(A_n)$ arranged in non-increasing order. With these results in mind, it is straightforward to see that

\[
\{ \hat{B}_n \}_n \sim_\lambda (f, G) \iff \{ \hat{A}_n \}_n \sim_\sigma (f, G),
\]

\[
\{ B_n \}_n \sim_\lambda (f, G) \iff \{ A_n \}_n \sim_\sigma (f, G),
\]

and the thesis is proved.

\[\square\]

### 4.2 Spectral analysis of the matrices $A_n$ and $A_n^p$ by the extradimensional approach

Here we come back to the study of the spectral distribution of $\{ \hat{A}_n \}_n$ and then of $\{ A_n \}_n$, by using the extradimensional approach (we borrowed the expression ‘extradimensional’ from a conversation with Eugene Tyrtshnikov). Indeed, thanks to Theorems 2.5, 2.6 and to property c1), the following results hold

\[
\{ n_1 M_{n_1}^{p-1} \}_n \sim_\lambda (m_{p-1}(\theta_1), [-\pi, \pi]),
\]

\[
\{ n_2 M_{n_2}^{p-1} \}_n \sim_\lambda (m_{p-1}(\theta_2), [-\pi, \pi]),
\]

\[
\left\{ \frac{1}{n_1} S_{n_1}^p \right\}_n \sim_\lambda (s_p(\theta_1) = m_{p-1}(\theta_1)(2 - 2 \cos(\theta_1)), [-\pi, \pi]),
\]

\[
\left\{ \frac{1}{n_2} S_{n_2}^p \right\}_n \sim_\lambda (s_p(\theta_2) = m_{p-1}(\theta_2)(2 - 2 \cos(\theta_2)), [-\pi, \pi]).
\]

Note that

\[
M_{n_1}^{p-1} = H_1 \hat{M}_{n_1}^{p-1} H_1^T,
\]

\[
M_{n_2}^{p-1} = H_2^T \hat{M}_{n_2}^{p-1} H_2,
\]

where

\[
H_1 = \begin{bmatrix} I_1 & 0_1 \end{bmatrix}
\]

(4.12)

with $0_1 = [0, \ldots, 0]^T \in \mathbb{R}^{n_1+p-1}$ and $I_1 \in \mathbb{R}^{(n_1+p-1)\times(n_1+p-1)}$, while

\[
H_2 = \begin{bmatrix} I_2 & 0_2 \end{bmatrix}
\]

(4.13)

with $0_2 = [0, \ldots, 0] \in \mathbb{R}^{n_2+p-1}$ and $I_2 \in \mathbb{R}^{(n_2+p-1)\times(n_2+p-1)}$. Because of relations (4.11), we can apply Theorem 4.3 to $\{ n_1 \hat{M}_{n_1}^{p-1} \}_n$ and $\{ n_2 \hat{M}_{n_2}^{p-1} \}_n$. Thus, by exploiting relations (4.9)-(4.10) and assuming $n = (n_1, n_2) = (n_1, n_2)n$, $n \in \mathbb{N}$, $n_1, n_2 \in \mathbb{Q}$, we obtain

\[
\left\{ \hat{A}_n^{(1,1)} \right\}_n = \left\{ \hat{M}_{n_1}^{p-1} \otimes S_{n_1}^p \right\}_n \sim_\lambda \left( \frac{n_2}{n_1} m_{p-1}(\theta_1)(m_{p-1}(\theta_2)(2 - 2 \cos(\theta_2)), [-\pi, \pi]) \right)
\]

\[
\left\{ \hat{A}_n^{(2,2)} \right\}_n = \left\{ \hat{S}_{n_1}^p \otimes \hat{M}_{n_2}^{p-1} \right\}_n \sim_\lambda \left( \frac{n_1}{n_2} m_{p-1}(\theta_2)(m_{p-1}(\theta_1)(2 - 2 \cos(\theta_1)), [-\pi, \pi]) \right).
\]

With the aim of computing the symbol of blocks $\{ \hat{A}_n^{(1,1)} \}_n$ and $\{ \hat{A}_n^{(2,2)} \}_n$ let us start computing the symbol of $\{ \hat{A}_n^{p} \}_n$. Thanks to the relations (2.2)-(2.3) between B-splines and cardinal B-splines, we know that

\[
N_i^{p-1}(t_i) = \phi_{p-1}(n_1 t_i - i + p), \quad i = p, \ldots, n_1,
\]

\[
(N_j^{p}(t_j))' = n_1 \phi_p'(n_1 t_j - j + p + 1), \quad j = p + 1, \ldots, n_1.
\]

Then we can write the principal submatrix of $\hat{A}_n^{p}$ corresponding to indices $p + 1, \ldots, n_1$ as follows

\[
\hat{A}_n^{p}_{i,j=p+1} = n_1 \int_0^1 \phi_{p-1}(n_1 t_i - i + p) \phi_p'(n_1 t_j - j + p + 1) dt_1,
\]

\[
= n_1 \int_0^1 \phi_{p-1}(n_1 t_i - i + p) \phi_p'(n_1 t_j - j + p + 1) dt_1,
\]

\[
= \int_R \phi_{p-1}(t_1) \phi_p'(t_1 + i - j + 1) dt.
\]

15
The second equality is obtained exploiting the local support property \textbf{b1}) for cardinal B-splines, while last step is the result of the following change of variable $t_1 \rightarrow n_1 t_1 - i + p$. The entries of $\hat{A}^p_{n_1} n_{j=p+1}$ depend only on the difference $i - j$, i.e., it is a Toeplitz matrix, and precisely

$$
\left[ \hat{A}^p_{n_1} \right]_{i,j=p+1}^{n_1} = T_{n_1-p}(\tilde{\alpha}_p),
$$

where

$$
\tilde{\alpha}_p(\theta_1) = \sum_{k \in \mathbb{Z}} \left( \int_{\mathbb{R}} \phi_{p-1}(t) \phi'_p(t + k + 1) dt \right) e^{ik\theta_1}.
$$

Making use of property \textbf{b3}) with $t + k + 1$ in place of $t$, we obtain $\phi'_p(t + k + 1) = \phi_{p-1}(t + k + 1) - \phi_{p-1}(t + k)$. Hence $\tilde{\alpha}_p(\theta_1)$ can be rewritten as

$$
\tilde{\alpha}_p(\theta_1) = \sum_{k \in \mathbb{Z}} \left( \int_{\mathbb{R}} \phi_{p-1}(t) \phi_{p-1}(t + k) dt \right) e^{ik\theta_1} - \sum_{k \in \mathbb{Z}} \left( \int_{\mathbb{R}} \phi_{p-1}(t) \phi_{p-1}(t + k) dt \right) e^{i(k-1)\theta_1} - \sum_{k \in \mathbb{Z}} \left( \int_{\mathbb{R}} \phi_{p-1}(t) \phi_{p-1}(t + k) dt \right) e^{ik\theta_1} - (e^{-i\theta_1} - 1) \sum_{k \in \mathbb{Z}} \left( \int_{\mathbb{R}} \phi_{p-1}(t) \phi_{p-1}(t + k) dt \right) e^{ik\theta_1}.
$$

By computing the inner product in the last equality and taking into account property \textbf{b6}), with $r_1 = r_2 = 0$, $q_1 = q_2 = p - 1$, and $\tau = k$, we deduce

$$
\int_{\mathbb{R}} \phi_{p-1}(t) \phi_{p-1}(t + k) dt = \phi_{2p-1}(p - k),
$$

which, by virtue of Theorem 2.5, implies the following identity

$$
\tilde{\alpha}_p(\theta_1) = m_{p-1}(\theta_1)(e^{-i\theta_1} - 1).
$$

Note that $T_{n_1-p}(\tilde{\alpha}_p)$ is a principal submatrix of both $\hat{A}^p_{n_1}$ and $T_{n_1+p}(\tilde{\alpha}_p)$ and so

$$
\hat{A}^p_{n_1} = T_{n_1+p}(\tilde{\alpha}_p) + R_{n_1}, \quad \text{rank}(R_{n_1}) = o(n_1 + p).
$$

From Theorem 2.4, the sequence $\{R_{n_1}\}_{n_1}$ is a zero distributed matrix-sequence, i.e., $\{R_{n_1}\}_{n_1} \sim_{\sigma} 0$ and therefore, by GLT5, $\{R_{n_1}\}_{n_1}$ is a GLT sequence with symbol identically zero. Using GLT3, also $\{T_{n_1+p}(\tilde{\alpha}_p)\}_{n_1}$ is a GLT sequence with symbol $\tilde{\alpha}_p$ and then, by GLT2, the sequence $\{T_{n_1+p}(\tilde{\alpha}_p) + R_{n_1}\}_{n_1}$ is still a GLT sequence with the same symbol. Consequently, by GLT1, we find

$$
\{ \hat{A}^p_{n_1} \}_{n_1} \sim_{\sigma} (\tilde{\alpha}_p(\theta_1), [-\pi, \pi]).
$$

Similarly, we can prove that

$$
\{ \hat{A}^p_{n_2} \}_{n_2} \sim_{\sigma} (\tilde{\alpha}_p(\theta_2), [-\pi, \pi]).
$$

Therefore,

$$
\left\{ \hat{A}^{(1,2)}_{n_1} \right\}_{n} = \left\{ \hat{A}^p_{n_1} \otimes \hat{A}^p_{n_2} \right\}_{n} \sim_{\sigma} (\tilde{\alpha}_p(\theta_1) \tilde{\alpha}_p(\theta_2), [-\pi, \pi]^2),
$$

where

$$
\tilde{\alpha}_p(\theta_1) \tilde{\alpha}_p(\theta_2) = m_{p-1}(\theta_1) m_{p-1}(\theta_2) (e^{-i\theta_1} - 1)(e^{-i\theta_2} - 1).
$$

Now, from the above discussion and from the comments in Subsection 2.4 it is easy to convince that $\hat{A}^{(i,j)}_{n_1}$, $i,j = 1, 2$ is a 2-level Toeplitz matrix up to a low-rank perturbation. More precisely, $\hat{A}^{(i,j)}_{n_1} = T_n(f_{ij}) + E^{(i,j)}_{n_1}$, $i,j = 1, 2$, where $T_n(f_{ij})$ is a 2-level Toeplitz matrix generated by $f_{ij} : [-\pi, \pi]^2 \rightarrow \mathbb{C}$, $i,j = 1, 2$, with

$$
f_{11}(\theta_1, \theta_2) = \frac{\nu_2}{\nu_1} m_{p-1}(\theta_1) m_{p-1}(\theta_2)(2 - 2\cos(\theta_2)),
$$

$$
f_{12}(\theta_1, \theta_2) = -m_{p-1}(\theta_1) m_{p-1}(\theta_2)(e^{-i\theta_1} - 1)(e^{-i\theta_2} - 1),
$$

$$
f_{21}(\theta_1, \theta_2) = m_{p-1}(\theta_1) m_{p-1}(\theta_2)(-\hat{\theta}_1, -\hat{\theta}_2),
$$

$$
f_{22}(\theta_1, \theta_2) = \frac{\nu_1}{\nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2)(2 - 2\cos(\theta_1)).
$$
Furthermore, through a proper permutation matrix $\Pi$ of size $2\hat{n}$, $\hat{n} = (n_1 + p)(n_2 + p)$, we can write

$$\Pi \tilde{A}_n \Pi^T = \Pi \begin{bmatrix} T_n(f_{11}) + E_n^{(1,1)} & T_n(f_{12}) + E_n^{(1,2)} \\ T_n(f_{21}) + E_n^{(2,1)} & T_n(f_{22}) + E_n^{(2,2)} \end{bmatrix} \Pi^T = T_n(f) + E_n,$$

where $f : [-\pi, \pi]^2 \to \mathbb{C}^{2 \times 2}$ is defined as follows

$$f(\theta_1, \theta_2) = \begin{bmatrix} f_{11}(\theta_1, \theta_2) & f_{12}(\theta_1, \theta_2) \\ f_{21}(\theta_1, \theta_2) & f_{22}(\theta_1, \theta_2) \end{bmatrix} = m_{p-1}(\theta_1)m_{p-1}(\theta_2) \begin{bmatrix} \frac{\nu}{\nu_2} (2 - 2 \cos(\theta_2)) & -(e^{-i\theta_1} - 1)(e^{-i\theta_2} - 1) \\ -(e^{i\theta_1} - 1)(e^{i\theta_2} - 1) & \frac{\nu}{\nu_2} (2 - 2 \cos(\theta_1)) \end{bmatrix},$$

while $E_n$ is a low-rank perturbation whose rank is $o(2\hat{n})$. Therefore, $\Pi \tilde{A}_n \Pi^T$ is a low-rank perturbation of a 2-level block Toeplitz matrix associated to the $2 \times 2$ matrix-valued function $f$. To write explicitly the permutation matrix $\Pi$, let us define by $e_j$, $j = 1, \ldots, 2\hat{n}$ the $j$-th column of the identity matrix of size $2\hat{n}$ and by $\pi_j$, $j = 1, \ldots, 2\hat{n}$ the $j$-th column of $\Pi$. Then,

$$\pi_j = \begin{cases} e_{2j-1} & j = 1, \ldots, \hat{n} \\ e_{2(j-\hat{n})} & j = \hat{n} + 1, \ldots, 2\hat{n} \end{cases}.$$

In other words, $\Pi$ is the $2\hat{n} \times 2\hat{n}$ matrix whose first $\hat{n}$ columns are the odd columns of the identity matrix of size $2\hat{n}$, while the remaining ones are the even columns of the same matrix.

Note that $f$ is an Hermitian matrix-valued function, then because of Theorem 2.3 (with $d = 2$, $s = 2$) it holds that $\{T_n(f)\}_n \sim_\lambda (f, [-\pi, \pi]^2)$. To compute the symbol of $\{\Pi \tilde{A}_n \Pi^T\}_n$, or equivalently of $\{\tilde{A}_n\}_n$, we will use Corollary 3.4 in [11] concerning the spectral distribution of multilevel block Toeplitz sequences plus low-rank perturbations. Without going into details, we only recall that, as stated in Corollary 3.4 in [11], the spectral distribution of a multilevel block Toeplitz sequence is not affected by a low-rank perturbation. On this basis we can conclude that $\{\tilde{A}_n\}_n$ and $\{T_n(f)\}_n$ have the same spectral distribution, i.e,

$$\{\tilde{A}_n\}_n \sim_\lambda (f, [-\pi, \pi]^2). \tag{4.14}$$

To retrieve the symbol of the original matrix-sequence $\{A_n\}_n$ we show that $A_n$ and $\tilde{A}_n$ are linked by means of a projection matrix and then use Theorem 4.3.

To write explicitly the projection matrix which links $A_n$ and $\tilde{A}_n$, let us start observing that

$$A_{n_1}^p = H_1 \tilde{A}_{n_1}^p, \quad A_{n_2}^p = \tilde{A}_{n_2}^p H_2,$$

where $H_1$ and $H_2$ are defined in (4.12) and (4.13), respectively. Therefore,

$$A_{n_1}^p \otimes A_{n_2}^p = (H_1 \otimes \tilde{I}_2)(\tilde{A}_{n_1}^p \otimes \tilde{A}_{n_2}^p)(\tilde{I}_1 \otimes H_2),$$

where $\tilde{I}_1$, $\tilde{I}_2$ are the identity matrices of size $n_1 + p$ and $n_2 + p$, respectively. Moreover, relations (4.11) imply that

$$M_{n_1}^{p-1} \otimes S_{n_2}^p = (H_1 \otimes \tilde{I}_2)(\tilde{M}_{n_1}^{p-1} \otimes \tilde{S}_{n_2}^p)(H_1^T \otimes \tilde{I}_2),$$

$$S_{n_1}^p \otimes M_{n_2}^{p-1} = (\tilde{I}_1 \otimes H_2^T)(\tilde{S}_{n_1}^p \otimes \tilde{M}_{n_2}^{p-1})(\tilde{I}_1 \otimes H_2),$$

and hence, putting together equations (4.15) and (4.16), we can write

$$A_n = P_n^T \tilde{A}_n P_n,$$

with

$$P_n = \begin{bmatrix} H_1^T \otimes \tilde{I}_2 & \mathcal{O}_1 \\ \mathcal{O}_2 & \tilde{I}_1 \otimes H_2 \end{bmatrix},$$

where $\mathcal{O}_1$ is the identically zero matrix of size $(n_1 + p)(n_2 + p) \times (n_1 + p)(n_2 + p - 1)$, while $\mathcal{O}_2$ is the identically zero matrix of size $(n_1 + p)(n_2 + p) \times (n_1 + p - 1)(n_2 + p)$. 

17
Recalling relation (4.14) and applying Theorem 4.3, we can conclude that

\[ \{A_n\}_{n} \sim_\lambda (f, [-\pi, \pi]^2). \]

Since \( f \) is a two-by-two matrix-valued symbol, we have to study its eigenvalue functions. First of all let us observe that \( \det(f(\theta_1, \theta_2)) = 0 \), which means that \( f \) is a rank-1 symbol and one of its eigenvalue functions, say \( \lambda_1(f(\theta_1, \theta_2)) \), is identically zero. Such a spectral behaviour is in line with the theoretical findings on the continuous curl-curl operator which has an infinite dimensional kernel. Because of its rank-1 nature, we can write \( f \) as the following dyad

\[ f(\theta_1, \theta_2) = \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \begin{bmatrix} \nu_2(e^{-i\theta_2} - 1) \\ -\nu_1(e^{i\theta_1} - 1) \end{bmatrix} \begin{bmatrix} \nu_2(e^{i\theta_2} - 1) \\ -\nu_1(e^{-i\theta_1} - 1) \end{bmatrix}. \]

Then we can conclude that the non identically zero eigenvalue of \( f(\theta_1, \theta_2) \) is the trace of the matrix that is

\[ \lambda_2(f(\theta_1, \theta_2)) = \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \left( v^H(\theta_1, \theta_2) v(\theta_1, \theta_2) \right) \]

\[ = \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \left( \nu_2^2(2 - 2 \cos(\theta_2)) + \nu_1^2(2 - 2 \cos(\theta_1)) \right). \]

This second eigenvalue is nothing but the symbol of the Laplacian operator discretized by means of B-splines and as such it has a nice connection with the continuous operator; indeed the curl-curl operator is expected to behave as a second order differential operator on the complement of the kernel. Being \( f \) a dyad, we can also easily compute the eigenvectors associated to \( \lambda_1(f(\theta_1, \theta_2)) \) and \( \lambda_2(f(\theta_1, \theta_2)) \) as follows

\[ z_1(\theta_1, \theta_2) = \frac{1}{\sqrt{v^H(\theta_1, \theta_2) v(\theta_1, \theta_2)}} \begin{bmatrix} \nu_1(e^{i\theta_1} - 1) \\ \nu_2(e^{-i\theta_2} - 1) \end{bmatrix}, \]

\[ z_2(\theta_1, \theta_2) = \frac{1}{\sqrt{v^H(\theta_1, \theta_2) v(\theta_1, \theta_2)}} v(\theta_1, \theta_2). \]

At this point we can compute the symbol of \( \{A_n^m\}_{n} \) as follows

\[ f^\mu(\theta_1, \theta_2) = f(\theta_1, \theta_2) + \frac{\mu}{\nu_1 \nu_2 n^2} \begin{bmatrix} m_{p-1}(\theta_1) m_p(\theta_2) \\ 0 \end{bmatrix} \begin{bmatrix} m_p(\theta_1) m_{p-1}(\theta_2) \\ 0 \end{bmatrix} \]

\[ = \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \left( v(\theta_1, \theta_2) v^H(\theta_1, \theta_2) + \frac{\mu}{n^2} D(\theta_1, \theta_2) \right), \quad (4.17) \]

where

\[ D(\theta_1, \theta_2) = \begin{bmatrix} m_p(\theta_2) \\ m_{p-1}(\theta_2) \\ m_{p-1}(\theta_1) \\ m_p(\theta_1) \end{bmatrix} \begin{bmatrix} 0 \\ 0 \end{bmatrix}. \]

Note that according to our notation \( f^0 \equiv f \). As already observed in [5], the following inequality is satisfied

\[ 0 < c \leq \frac{m_p(\theta)}{m_{p-1}(\theta)} \leq 1, \]

that is, \( \frac{m_p(\theta)}{m_{p-1}(\theta)} \) is a function well-separated from zero, uniformly with respect to \( \theta \in [0, \pi] \) and with respect to \( p \geq 1 \). Applying the well-known min-max theorem, we obtain

\[ \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \frac{\mu}{n^2} c \leq \lambda_1(f^\mu(\theta_1, \theta_2)) \leq \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \frac{\mu}{n^2}, \quad (4.18) \]
\[
\begin{align*}
\lambda_2(f^\mu(\theta_1, \theta_2)) &\geq \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \left( \mathcal{L}_{\nu_1, \nu_2}(\theta_1, \theta_2) + \frac{\mu}{n^2} \right), \\
\lambda_2(f^\mu(\theta_1, \theta_2)) &\leq \frac{1}{\nu_1 \nu_2} m_{p-1}(\theta_1) m_{p-1}(\theta_2) \left( \mathcal{L}_{\nu_1, \nu_2}(\theta_1, \theta_2) + \frac{\mu}{n^2} \right),
\end{align*}
\] (4.19)

where
\[
\mathcal{L}_{\nu_1, \nu_2}(\theta_1, \theta_2) = \nu^H(\theta_1, \theta_2) \nu(\theta_1, \theta_2) = \sum_{j=1}^2 \nu_j^2(2 - 2 \cos(\theta_j)),
\] (4.20)
is exactly the generating function of a pure discrete Laplacian. Indeed, when discretizing \( \delta = -\hat{c}_2^2 - \hat{c}_1^2 \) over \((0,1)^2\) with Dirichlet boundary conditions, by using the standard Finite Difference five point stencil with \( \nu_1 \nu_2 \) internal points in the \( x \) direction and \( \nu_2 \) internal points in the \( y \) direction, we end up with the two-level Toeplitz matrix \( T_n(f) \) where \( n = (\nu_1, \nu_2) \) and \( f(\theta_1, \theta_2) = \mathcal{L}_{\nu_1, \nu_2}(\theta_1, \theta_2) = \sum_{j=1}^2 \nu_j^2(2 - 2 \cos(\theta_j)) \), which is the same expression appearing in (4.20).

### 4.3 Numerical evidences

In this subsection we give numerical evidences of the spectral results obtained in the current section. More in detail, we show that the symbol of \( \{A_n^\mu\}_n \) is \( f^\mu(\theta_1, \theta_2) \) defined as in (4.17). Taking into consideration Remark 2.1, this numerical study can be done by comparing the eigenvalues of \( A_n^\mu \) with a sampling of the eigenvalue functions \( \lambda_1(f^\mu), \lambda_2(f^\mu) \). Actually, for our computations instead of \( \lambda_1(f^\mu), \lambda_2(f^\mu) \) we will use the corresponding approximation provided by the upper bounds in (4.18) and (4.19). In the following, such upper bounds will be denoted by \( \lambda_{1u}^{up}(f^\mu) \) and \( \lambda_{2u}^{up}(f^\mu) \), respectively.

Let us fix \( n = (\nu_1, \nu_2), \) with \( \nu_1, \nu_2 = 1, n \in \mathbb{N} \) and let us define the following equispaced grid on \([-\pi, \pi]^2\)
\[
G_{n,p} = \left\{ (\theta(j), \theta(k)) = \left( \frac{j \pi}{n + p - 1}, \frac{k \pi}{n + p} \right), \quad j = -(n + p - 1), \ldots, n + p - 1; \quad k = -(n + p), \ldots, n + p \right\}.
\]

In Figure 1(A)-1(B) we display the approximation of the eigenvalues functions \( \lambda_k(f^\mu), k = 1, 2 \) given by the upper bounds \( \lambda_{1u}^{up}(f^\mu) \) and \( \lambda_{2u}^{up}(f^\mu) \) on the mesh \( G_{n,p}, \) fixed \( n = 40, \) \( p = 3, \) \( \mu = 10^{-2} \).

![Figure 1: An approximation of the eigenvalues functions \( \lambda_k(f^\mu), k = 1, 2 \) given by \( \lambda_{1u}^{up}(f^\mu) \) and \( \lambda_{2u}^{up}(f^\mu) \) on the mesh \( G_{40,3} \), fixed \( \mu = 10^{-2} \).](image)

From now onwards, fixed \( k = 1, 2 \), we denote by \( \lambda_k^{up}(f^\mu)|_{G_{n,p}} \) the lexicographically ordered vector of all evaluations of \( \lambda_k^{up}(f^\mu) \) on \( G_{n,p}, \) i.e.,

\[
\lambda_k^{up}(f^\mu)|_{G_{n,p}} := \left[ \lambda_k^{up}(f^\mu(\theta_1^{-(n+p-1)}, \theta_2^{(n+p)})), \ldots, \lambda_k^{up}(f^\mu(\theta_1^{(n+p-1)}, \theta_2^{(n+p)})) \right],
\]

and by \( \lambda^{up}(f^\mu)|_{G_{n,p}} \) the vector of all evaluations of \( \lambda_k^{up}(f^\mu) \) on \( G_{n,p} \) varying \( k \), i.e.,

\[
\lambda^{up}(f^\mu)|_{G_{n,p}} := \left[ \lambda_{1u}^{up}(f^\mu)|_{G_{n,p}}, \lambda_{2u}^{up}(f^\mu)|_{G_{n,p}} \right].
\]
As a first evidence that \( \{A_n^\mu\}_n \) spectrally behaves as \( f^\mu(\theta_1, \theta_2) \), in Figure 2 we compare the eigenvalues of \( A_n^\mu \) with the evaluations of \( \lambda_k^\mu(f^\mu) \), \( k = 1, 2 \) at \( G_{n,p} \) contained in \( \lambda^{up}(f^\mu)|_{G_{n,p}} \) (ordered in ascending way). Here the parameters \( n, p, \mu \) have been fixed as in Figure 1. Let us observe that, as predicted by the theory, the eigenvalues of \( A_n^\mu \) mimic, up to outliers, the considered sampling of \( \lambda_k^\mu(f^\mu) \), \( k = 1, 2 \).

Aside from such a global comparison, since the following relation holds

\[ \text{esssup}_{[-\pi,\pi]} \lambda_1^{up}(f^\mu) < \text{essinf}_{[-\pi,\pi]} \lambda_2^{up}(f^\mu), \]

again according to Remark 2.1, we can provide a more accurate analysis of the spectrum of \( A_n^\mu \) determining how many blocks it is made up of and how many eigenvalues contains each block. We expect that, up to outliers, a half of the eigenvalues of \( A_n^\mu \) behaves as \( \lambda_1^{up}(f^\mu) \) and a half of them behaves as \( \lambda_2^{up}(f^\mu) \). More in detail, if we denote by

\[ m_k = \min_{G_{n,p}} \lambda_k^{up}(f^\mu), \quad M_k = \max_{G_{n,p}} \lambda_k^{up}(f^\mu), \]

we expect the eigenvalues of \( A_n^\mu \) to identify 2 blocks and to verify

\begin{align*}
\# \{ i : \lambda_i(A_n^\mu) \in [m_1, M_1] \} &= \frac{\text{dim}(A_n^\mu)}{2} + o(\text{dim}(A_n^\mu)), \\
\# \{ i : \lambda_i(A_n^\mu) \in [m_2, M_2] \} &= \frac{\text{dim}(A_n^\mu)}{2} + o(\text{dim}(A_n^\mu)), \tag{4.21}
\end{align*}

For instance, for \( n, p, \mu \) as in Figure 1 we have \( \text{dim}(A_n^\mu) = 3612 \), then we expect that approximately 1806 eigenvalues of \( A_n^\mu \) behave as \( \lambda_1^{up}(f^\mu) \) and 1806 eigenvalues of them behaves as \( \lambda_2^{up}(f^\mu) \). Indeed, a direct computation show that,

\begin{align*}
\# \{ i : \lambda_i(A_n^\mu) \in [m_1, M_1] \} &= 1848, \\
\# \{ i : \lambda_i(A_n^\mu) \in [m_2, M_2] \} &= 1659,
\end{align*}

and this is in line with the relations in (4.21) since the order of what is missing/exceeding is infinitesimal in the dimension of \( A_n^\mu \). A confirmation of this behaviour can be found in Tables 1-2 in which we compare the actual number of eigenvalues of \( A_n^\mu \) contained in the intervals \([m_1, M_1]\) and \([m_2, M_2]\), respectively, with the expected number \( \frac{\text{dim}(A_n^\mu)}{2} \). In such way, we succeed in counting the outliers of \( A_n^\mu \) in \([m_1, M_1]\) and \([m_2, M_2]\) and show that their cardinality behaves as \( o(\text{dim}(A_n^\mu)) \).

A further evidence that, \( \{A_n^\mu\}_n \) spectrally behaves as \( f^\mu(\theta_1, \theta_2) \) can be obtained by comparing the eigenvalues of \( A_n^\mu \) with the elements of \( \lambda^{up}(f^\mu)|_{G_{n,p}} \) according to the following matching algorithm:

- for a fixed \( \xi \in \Lambda(A_n^\mu) \) find \( \tilde{\eta} \in \lambda^{up}(f^\mu)|_{G_{n,p}} \) such that
  \[ \|\xi - \tilde{\eta}\| = \min_{\eta \in \lambda^{up}(f^\mu)|_{G_{n,p}}} \|\xi - \eta\|, \]
  where \( \Lambda(A_n^\mu) \) is the set of all the eigenvalues of \( A_n^\mu \) and \( \|\cdot\| \) is the standard euclidian norm.

Figure 2: Comparison of the eigenvalues of \( A_n^\mu \) (•) with \( \lambda^{up}(f^\mu)|_{G_{n,p}} \) ordered in ascending way (◦), when \( n = 40, p = 3, \mu = 10^{-2} \) (matrix-size 3612).
Making use of the previous algorithm, in Figure 3 we compare the eigenvalues of $A^\mu_n$ contained in the interval $[m_1, M_1]$ with the expected number $\dim(A^\mu_n)/2$.

4.4 Numerical difficulties when solving large linear systems with IgA (stabilized) curl-curl matrices

In this subsection, in the light of the spectral analysis given so far, we give a concise account of the behaviour of classical and more advanced solvers for the solution of the linear systems whose coefficient matrix is obtained from $A^\mu_n$ in (3.7) imposing the so-called ‘essential’ boundary conditions (see [19] for more details) and varying the different parameters, $n$, $p$, $\mu$. Below, for simplicity, we refer to this matrix of size $2(n_1 + p - 1)(n_2 + p - 2) \times 2(n_1 + p - 2) (n_2 + p - 1)$ again as $A^\mu_n$ and we fix $n = (n,n)$ and $p = (p,p)$. In detail, we discuss the performances of the conjugate gradient (CG) and of a preconditioner for the CG, whose definition is guided by the knowledge of the symbol of $\{A^\mu_n\}_n$ and is given by

$$P_n^\mu = \begin{bmatrix} T_{n+p-1}(m_{p-1}(\theta_1))@T_{n+p-2}(m_{p-1}(\theta_2)) \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \circ \cir..
i.e., its entries are nothing but evaluations of cardinal B-splines. Moreover, due to its tensor product nature, the linear system whose coefficient matrix is the preconditioner (4.22) is easily solvable and computationally cheap. Indeed, by the properties of Kronecker product we have

\[(P_n[P])^{-1} = \begin{bmatrix}
T^{-1}_{n+p-1}(m_{p-1}(\theta_1)) \otimes T^{-1}_{n+p-2}(m_{p-1}(\theta_2)) \\
0 \\
T^{-1}_{n+p-2}(m_{p-1}(\theta_1)) \otimes T^{-1}_{n+p-1}(m_{p-1}(\theta_2))
\end{bmatrix},\]

and the diagonal blocks of \((P_n[P])^{-1}\) can be solved by means of an LU factorization which is optimal for banded matrices, i.e., linear in the matrix-size (and quadratic in the bandwidth). Therefore, the computational cost for solving a linear system with coefficient matrix (4.22) is linear in the matrix-size \(2^p n^p\).

Regarding the stopping criterion for the CG, we use \(\|r_k\|_2 / \|r_0\|_2 < 10^{-7}\), where \(r_k\) is the residual vector after \(k\) iterations. The initial guess is always chosen as the zero vector. For our test examples, we choose the vector solution \(\tilde{u}\) as an equispaced sampling of the function

\[\varphi(x_1, x_2) = \sin(3x_1) + \sin(3x_2), \quad (x_1, x_2) \in (0, \pi)^2,\]

and as right-hand side \(b = A_n[\tilde{u}]\). Moreover, we test the considered methods both in terms of iterations and of relative approximation error defined as

\[\text{Error} = \frac{\|u - \tilde{u}\|_2}{\|u\|_2},\]

where \(u\) is the numerical solution.

When \(\mu = 0\), as computed in Subsection 4.2, the number of eigenvalues of \(A_n\) in a neighborhood of zero is given by \(\frac{\dim(A_n)}{2} + o(\dim(A_n))\), then the considered matrices represent the discretization of an ill-posed problem [6]. In this case, the CG method will converge to the minimum norm solution: see Table 3 where it is clear from the error that the solution provided by the CG is far from \(\tilde{u}\).

Hence, as in a standard Tikhonov for image deblurring and denoising [6], we need a kind of regularization and this is done by using the parameter \( \mu > 0 \). In any case \( \mu > 0 \) has to be chosen small and therefore also the matrices \( A^\mu_n \) are very ill-conditioned and possess \( \frac{\text{dim}(A^\mu_n)}{2} + o(\text{dim}(A^\mu_n)) \) eigenvalues in a neighborhood of the interval \((m_1, M_1)\), with both \( m_1 \) and \( M_1 \) converging linearly to zero as \( \mu \) goes to zero (see (4.18) and the numerical experiments in Subsection 4.3). The latter choice has two consequences:

- if we fix \( \mu > 0 \), but 'small', then the CG method is slow and this slow behaviour is due to a subspace of large dimension. As a result, we see a significant growth of the iteration number with \( n \) (refer to Table 4);
- if we fix the size \( n \), then we see a deterioration of the error as \( \mu \) becomes smaller and the number of iterations is no more reliable (refer to Table 5).

However, even when we fix the size \( n \) and we take \( \mu > 0 \) not so 'small', there is a third source of ill-conditioning hidden in the degree \( p \) of the B-spline. Such a behaviour is confirmed in Table 6 for \( \mu = 10^{-1} \) and \( n = 64 \). On the other hand, as shown in Table 7, using \( p^p_n \) as preconditioner the number of iterations of the CG reveals less sensible with respect to the degree \( p \).

Table 6: CG iterations and approximation error when \( \mu = 10^{-1}, n = 64, p = 1, \ldots, 5. \)

These numerical results can be spectrally justified as follows. As for the symbol of the IgA stiffness matrix-sequence (recall Remark 2.7), it can be shown that the eigenvalue functions \( \lambda_j(f^\mu(\theta_1, \theta_2)), j = 1, 2 \) satisfy the following properties:

(i) for \( \mu = 0 \) \( \lambda_2(f^\mu(\theta_1, \theta_2)) \) has an analytic zero in \((\theta_1, \theta_2) = (0, 0)\) of order 2, \( \lambda_1(f^\mu(\theta_1, \theta_2)) \) is identically zero;
Table 7: Iteration number of the CG preconditioned with $P_n^{[p]}$ (PCG) and approximation error when $\mu = 10^{-1}$, $n = 64$, $p = 1, \ldots, 5$.

(ii) both $\lambda_1(f^\mu(\theta_1, \theta_2))$ and $\lambda_2(f^\mu(\theta_1, \theta_2))$ possess infinitely many numerical exponential zeros at the points $(\theta_1, \theta_2)$ with $\theta_j = \pi$ when $p$ becomes large.

For fixed small $\mu$, properties (i) – (ii) imply that the small eigenvalues of $A_n^\mu$ are related both with subspaces of low and high frequencies. As confirmed by the slowing down of the iteration number as $p$ increases, the preconditioner $P_n^{[p]}$ is acting in the high frequencies. Following the approach in [5], the next step will be to combine this preconditioning with some other classic iterative solver able to cut the ill-conditioning in the low-frequencies, that is to apply a so-called multi-iterative method (see [20]), a strategy made up of different basic iterative solvers having complementary spectral behaviour.

The analysis of such methods together with other techniques guided by the knowledge of the symbol are considered in a forthcoming paper.

5 Conclusions and future works

We have studied structural and spectral features of linear systems of equations arising from Galerkin approximations of $H(curl)$ elliptic variational problems, based on the Isogeometric approach. First, we considered a Compatible B-Splines discretization based on a discrete De Rham sequence and we identified the structure of the resulting matrix $A_n$, which shows a two-by-two pattern and is a principal submatrix of a two-by-two block matrix, where each block is two-level banded, almost Toeplitz, and where the bandwidths grow linearly with the degree of the B-splines.

Looking at the coefficients in detail and making use of the theory of the GLT sequences, we computed the symbol of each of these blocks, that is a function describing asymptotically, i.e., for $n$ large enough, the spectrum of each block. From this knowledge and thanks to some new spectral tools we recovered the symbol of $\{A_n\}_n$ which as expected is a two-by-two matrix-valued bivariate trigonometric polynomial. In particular, there is a nice elegant connection with the continuous operator which has an infinite dimensional kernel, and in fact the symbol is a dyad having one eigenvalue like the one of the IgA Laplacian, and one identically zero eigenvalue: as a consequence, we proved that one half of the spectrum of $A_n$, for $n$ large enough, is very close to zero and this represents the discrete counterpart of the infinite dimensional kernel of the continuous operator. From the latter information, we gave a detailed spectral analysis of the matrices $A_n$, which is fully confirmed by several numerical evidences.

Finally, by taking into consideration the GLT theory and making use of the spectral results, we furnished indications on the convergence features of known iterative solvers and we suggested proper iterative techniques for the numerical solution of the involved linear systems.

The spectral analysis presented in this paper will provide a strong guidance for the forthcoming works. On the one hand we will perform a more detailed study of the multi-iterative approach discussed at the end of Subsection 4.4 as a way to overcome the ill-conditioning related to the matrix-size and the degree of the B-splines. On the other hand, we will face the ill-conditioning related to the stabilization parameter using some sort of splitting strategy able to isolate the huge kernel of the curl-curl operator from its orthogonal where the operator behaves like a second order operator. In this direction we will extend also in the IgA framework the so-called auxiliary space preconditioning (introduced for finite elements in [14]) whose main idea consists of transferring the original problem to one or more simpler spaces (called auxiliary spaces) where the problem can be solved in an easier way, and then to transfer back the solution correcting the mismatch between the original space and the auxiliary spaces with some smoothing scheme.
