## Abstract

This paper concerns the spectral analysis of matrix-sequences which can be written as a non-Hermitian perturbation of a given Hermitian matrix-sequence. The main result reads as follows. Suppose that  $X_n$  is a Hermitian matrix of size  $n$  and that  $\{X_n\}_n \sim_\lambda f$ , i.e., the matrix-sequence  $\{X_n\}_n$  enjoys an asymptotic spectral distribution, in the Weyl sense, described by a Lebesgue measurable function  $f$ ; if  $\|Y_n\|_2 = o(\sqrt{n})$  with  $\|\cdot\|_2$  being the Schatten 2 norm, then  $\{X_n + Y_n\}_n \sim_\lambda f$ . In a previous paper by Leonid Golinskii and the second author a similar result was proved, but under the technical restrictive assumption that the involved matrix-sequences  $\{X_n\}_n$  and  $\{Y_n\}_n$  are uniformly bounded in spectral norm. Nevertheless, the result had a remarkable impact in the analysis of both spectral distribution and clustering of matrix-sequences arising from various applications, including the numerical approximation of partial differential equations (PDEs) and the preconditioning of PDE discretization matrices. The new result considerably extends the spectral analysis tools provided by the former one, and in fact we are now allowed to analyse variable-coefficient PDEs with unbounded coefficients, preconditioned matrix-sequences, etc. A few selected applications are considered, extensive numerical experiments are discussed, and a further conjecture is illustrated at the end of the paper.

*Keywords:* Perturbation results, spectral distribution in the Weyl sense, approximation of PDEs, preconditioning

## 1 Introduction

A *Matrix-Sequence*  $\{A_n\}_n$  is an ordered collection of complex matrices such that  $A_n \in \mathbb{C}^{n \times n}$ . We will denote by  $\mathcal{E}$  the space of all matrix-sequences,

$$\mathcal{E} := \{\{A_n\}_n : A_n \in \mathbb{C}^{n \times n}\}.$$

It is often observed in practice that matrix-sequences  $\{A_n\}_n$  arising from the numerical discretization of linear differential equations possess a *Spectral Symbol*, that is, a measurable function describing the asymptotic distribution of the eigenvalues of  $A_n$  in the Weyl sense [9, 20, 33]. We recall that a spectral symbol associated with a sequence  $\{A_n\}_n$  is a measurable function  $f : D \subseteq \mathbb{R}^q \rightarrow \mathbb{C}$ ,  $q \geq 1$ , satisfying

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n F(\lambda_i(A_n)) = \frac{1}{l(D)} \int_D F(f(x)) dx$$

for every continuous function  $F : \mathbb{C} \rightarrow \mathbb{C}$  with compact support, where  $D$  is a measurable set with finite Lebesgue measure  $l(D) > 0$  and  $\lambda_i(A_n)$  are the eigenvalues of  $A_n$ . In this case we write

$$\{A_n\}_n \sim_\lambda f.$$

This paper concerns the spectral analysis of matrix-sequences which can be written as a non-Hermitian perturbation of a given Hermitian matrix-sequence. We prove several results on the spectral symbols of such matrix-sequences. We remind that the knowledge of the spectral symbol has a practical impact in obtaining fine estimates on the convergence speed of Krylov methods (see [4, 26]), when we face the problem of the efficient computation of the solution of large linear systems. Furthermore, especially in the context of generalized locally Toeplitz (GLT) matrix-sequences [20, 22, 21] arising in the approximation of partial differential equations (PDEs), the computation and analysis of the spectral symbol [14, 15, 16, 17] have been used for designing efficient solvers combining preconditioning and multigrid/multi-iterative methods (see [5, 11, 12, 24, 25] and references therein).

From the point of view of the applications the main result of this paper is the following.

**Theorem 1.1.** *Let  $\{X_n\}_n$  be a matrix-sequence such that each  $X_n$  is Hermitian and  $\{X_n\}_n \sim_\lambda f$ , where  $f$  is a measurable function defined on a subset of some  $\mathbb{R}^q$  with finite and positive Lebesgue measure. If  $\|Y_n\|_2 = o(\sqrt{n})$ , with  $\|\cdot\|_2$  being the Frobenius norm, then  $\{X_n + Y_n\}_n \sim_\lambda f$ .*

In a previous paper by Leonid Golinskii and the second author a similar result was proved [23, Theorem 3.4], but under the technical restrictive assumption that the involved matrix-sequences  $\{X_n\}_n, \{Y_n\}_n$  are uniformly bounded in spectral norm. Nevertheless, the result had a remarkable impact in the analysis of both spectral distribution and clustering of matrix-sequences arising from various applications, including the study of the zeros of orthogonal polynomials [27] and the computation of the spectral symbol of matrix-sequences belonging to the algebra generated by Toeplitz sequences [32]. However, the main application remains the numerical approximation of PDEs (and fractional PDEs) along with the preconditioning of the related discretization matrices [5, 6, 11, 12, 13]. Indeed, when the approximation of a differential operator of order  $k$  is considered, the matrices coming from the discretization of the lower order operators are usually of negligible norm and hence, in general,  $\{s_k A_n\}_n$  is exactly a sequence that can be written as a Hermitian dominant part plus a perturbation, where  $s_k = 1$  if  $k$  is even and  $s_k$  is the imaginary unit if  $k$  is odd.

The new result (Theorem 1.1) considerably extends the spectral analysis tools delivered by the former one [23], and in fact we are now allowed to analyze variable-coefficient PDEs with unbounded coefficients. Furthermore, Theorem 1.1 has an impact on the GLT theory, because it allows a generalization of property **GLT2** in [20, page 4] and [21, page 6] (see also Section 3). We remind that the GLT matrix-sequences form a  $*$ -algebra of matrix-sequences including Toeplitz sequences generated by  $L^1$  symbols [9], their algebra, and virtually any kind of matrix-sequences arising from the approximation by local methods (finite differences, finite elements, finite volumes, isogeometric analysis [10], etc.) of variable-coefficient differential and fractional operators.

The paper is organized as follows. The theory is developed in Section 2. Section 3 contains the essentials of the GLT theory, for dealing with approximated differential operators. In Section 4 a few selected applications are considered. Extensive numerical experiments are discussed in Section 5 to show the correctness of the theory. A final Section 6 summarizes the findings of the paper and a conjecture, supported by numerical experiments, is illustrated.

## 2 Perturbation Results

In order to prove our main result, we need to introduce two distances on the space  $\mathcal{E}$  and some bounds. First of all, we recall a known theorem due to Hoffman and Wielandt; see [7]. It shows that the Schatten 2-norm (also called Frobenius norm) of the difference of normal matrices is bounded both superiorly and inferiorly by the 2-norm of their eigenvalue differences in some order. Owing to this result, we can prove a second lemma that analyses the case where  $A$  is Hermitian while  $B$  is any matrix. In what follows, we denote by  $S_n$  the collection of all permutations  $\sigma$  of the set  $\{1, \dots, n\}$ .

**Theorem 2.1** (Hoffman-Wielandt). *Let  $A, B \in \mathbb{C}^{n \times n}$  be normal matrices. If  $\alpha_1, \alpha_2, \dots, \alpha_n$  and  $\beta_1, \beta_2, \dots, \beta_n$  are the eigenvalues of  $A$  and  $B$ , respectively, then*

$$\min_{\sigma \in S_n} \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2 \leq \|A - B\|_2^2 \leq \max_{\sigma \in S_n} \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2.$$

Moreover, if  $A$  is Hermitian,  $\alpha_1 \geq \alpha_2 \geq \dots \geq \alpha_n$  and  $\Re(\beta_1) \geq \Re(\beta_2) \geq \dots \geq \Re(\beta_n)$ , then

$$\sum_{i=1}^n |\alpha_i - \beta_i|^2 \leq \|A - B\|_2^2 \leq \sum_{i=1}^n |\alpha_i - \beta_{n-i}|^2.$$

**Lemma 2.2.** Let  $A$  be a Hermitian matrix and  $B$  be any matrix with eigenvalues  $\alpha_1, \alpha_2, \dots, \alpha_n$  and  $\beta_1, \beta_1, \dots, \beta_n$ , respectively. In this case,

$$\min_{\sigma \in S_n} \left( \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2 \right)^{1/2} \leq \sqrt{2} \|A - B\|_2.$$

*Proof.* By the Schur normal form, we are allowed to perform an orthonormal base change in order to transform the matrix  $B$  in upper triangular form. Indeed, such transformation does not change the eigenvalues, the Schatten 2-norm and the Hermitian nature of  $A$ . With an abuse of notations, we will continue to denote with  $A, B$  the matrices after the base change. We can thus decompose  $B$  into

$$B = D + iN + R$$

where  $D, N$  are real diagonal matrices, and  $R$  is a strictly upper triangular matrix. Moreover, any square matrix  $Y$  can be decomposed in terms of its real and imaginary parts as  $Y = \Re(Y) + i \Im(Y)$ , where  $\Re(Y) = \frac{1}{2}(Y + Y^*)$  and  $\Im(Y) = \frac{1}{2i}(Y - Y^*)$ . Therefore we decompose  $A - B$  in terms of its real and imaginary parts, namely

$$\Re(A - B) = A - D - \frac{R + R^*}{2}, \quad \Im(A - B) = -N - \frac{R - R^*}{2i}.$$

Notice that  $N, R$  and  $R^*$  are element-wise disjoint, since  $N$  is diagonal,  $R$  is strictly upper triangular and  $R^*$  is strictly lower triangular. Moreover, if we decompose  $\beta_i = \mu_i + i\nu_i$  where  $\mu_i$  and  $\nu_i$  are real numbers, then we obtain

$$N = \text{diag}(\nu_i)_{i=1, \dots, n},$$

and, as a consequence,

$$\|\Im(A - B)\|_2^2 = \|N\|_2^2 + \frac{1}{4} (\|R\|_2^2 + \|R^*\|_2^2) = \sum_{i=1}^n \nu_i^2 + \frac{1}{2} \|R\|_2^2. \quad (1)$$

Using the triangular property of the norm, we can state that

$$\|\Re(A - B)\|_2 \geq \|A - D\|_2 - \frac{1}{2} \|R + R^*\|_2 = \|A - D\|_2 - \frac{1}{\sqrt{2}} \|R\|_2, \quad (2)$$

and owing to Theorem 2.1, we know that

$$\|A - D\|_2^2 \geq \sum_{i=1}^n (\alpha_i - \mu_i)^2. \quad (3)$$

In addition, denote by  $X, Y$  the real and imaginary parts of  $A - B$ , respectively. We can use the property of the trace  $Tr(XY) = Tr(YX)$  in the following sequence of identities:

$$\begin{aligned} \|A - B\|_2^2 &= \|X + iY\|_2^2 \\ &= Tr[(X + iY)^*(X + iY)] \\ &= Tr[(X - iY)(X + iY)] \\ &= Tr(X^2) + Tr(Y^2) - i[Tr(XY) - Tr(YX)] \\ &= \|\Re(A - B)\|_2^2 + \|\Im(A - B)\|_2^2. \end{aligned} \quad (4)$$

Finally, by exploiting (1)–(4), we prove the result as follows:

$$\begin{aligned}
\sum_i |\alpha_i - \beta_i|^2 &= \sum_i (\alpha_i - \mu_i)^2 + \sum_i \nu_i^2 \\
&\leq \|A - D\|_2^2 + \|N\|_2^2 \\
&\leq \left( \|\Re(A - B)\|_2 + \frac{1}{\sqrt{2}} \|R\|_2 \right)^2 + \|\Im(A - B)\|_2^2 - \frac{1}{2} \|R\|_2^2 \\
&= \|\Re(A - B)\|_2^2 + \sqrt{2} \|R\|_2 \|\Re(A - B)\|_2 + \|\Im(A - B)\|_2^2 \\
&\leq \|\Re(A - B)\|_2^2 + 2 \|\Im(A - B)\|_2 \|\Re(A - B)\|_2 + \|\Im(A - B)\|_2^2 \\
&\leq 2 (\|\Re(A - B)\|_2^2 + \|\Im(A - B)\|_2^2) \\
&= 2 \|A - B\|_2^2.
\end{aligned}$$

□

We could also prove that the permutation  $\sigma$  for which the minimum in Lemma 2.2 is attained is the one which sorts the eigenvalues accordingly to

$$\alpha_1 \leq \alpha_2 \leq \dots \leq \alpha_n, \quad \Re(\beta_1) \leq \Re(\beta_2) \leq \dots \leq \Re(\beta_n).$$

However, this additional information is not necessary to our purposes.

## 2.1 Distances on Sequences

The next definition introduces a pseudometric on  $\mathbb{C}^n$  which is known as the *Optimal Matching Distance* [7].

**Definition 2.3.** Given  $v, w \in \mathbb{C}^n$ , the optimal matching distance is defined as

$$d(v, w) := \min_{\sigma \in S_n} \max_{i=1, \dots, n} |v_i - w_{\sigma(i)}|.$$

We can modify the previous metric, and introduce a new function  $d'$  called *Modified Optimal Matching Distance*.

**Definition 2.4.** Given  $v, w \in \mathbb{C}^n$ , the modified optimal matching distance is defined as

$$d'(v, w) := \min_{\sigma \in S_n} \min_{i=1, \dots, n+1} \left\{ \frac{i-1}{n} + |v - w_{\sigma}|_i^\downarrow \right\},$$

where

$$|v - w_{\sigma}| = [|v_1 - w_{\sigma(1)}|, |v_2 - w_{\sigma(2)}|, \dots, |v_n - w_{\sigma(n)}|]$$

and  $|v - w_{\sigma}|_i^\downarrow$  is the  $i$ th greatest element in  $|v - w_{\sigma}|$ , with the convention  $|v - w_{\sigma}|_{n+1}^\downarrow := 0$ .

Given  $A \in \mathbb{C}^{n \times n}$ , let  $\Lambda(A) \in \mathbb{C}^n$  be the vector of the eigenvalues. We can extend the distances  $d, d'$  to matrices and sequences in the following ways.

**Definition 2.5.** Let  $d(\cdot, \cdot)$  and  $d'(\cdot, \cdot)$  be as in Definition 2.3 and 2.4, respectively. Given  $A, B \in \mathbb{C}^{n \times n}$ , we define

$$d(A, B) := d(\Lambda(A), \Lambda(B)), \quad d'(A, B) := d'(\Lambda(A), \Lambda(B)).$$

Given  $\{A_n\}_n, \{B_n\}_n \in \mathcal{E}$ , we define

$$d(\{A_n\}_n, \{B_n\}_n) := \limsup_{n \rightarrow \infty} d(A_n, B_n), \quad d'(\{A_n\}_n, \{B_n\}_n) := \limsup_{n \rightarrow \infty} d'(A_n, B_n).$$

It was proved in [2] that  $d'$  induces a complete pseudometric on  $\mathcal{E}$ , and one of the main result of the paper is reported below.

**Theorem 2.6.** *If  $\{A_n\}_n \sim_\lambda f$ , then*

$$d'(\{A_n\}_n, \{B_n\}_n) = 0 \iff \{B_n\}_n \sim_\lambda f.$$

Notice that  $d'(\{A_n\}_n, \{B_n\}_n) \leq d(\{A_n\}_n, \{B_n\}_n)$  for every pair of sequences  $\{A_n\}_n, \{B_n\}_n \in \mathcal{E}$ , and hence we have the following corollary.

**Corollary 2.7.** *If  $\{A_n\}_n \sim_\lambda f$ , then*

$$d(\{A_n\}_n, \{B_n\}_n) = 0 \implies \{B_n\}_n \sim_\lambda f.$$

## 2.2 Proof of the Main Result

We are now ready to prove our main result (Theorem 1.1).

*Proof of Theorem 1.1.* Throughout this proof, the eigenvalues of  $X_n$  will be denoted by  $\lambda_1, \dots, \lambda_n$  and the eigenvalues of  $X_n + Y_n$  by  $\mu_1, \dots, \mu_n$ . Owing to Lemma 2.2, we know that for any Hermitian matrix  $A$  with eigenvalues  $\alpha_i$  and any matrix  $B$  with eigenvalues  $\beta_i$ , it holds

$$\min_{\sigma \in S_n} \left( \sum_{i=1}^n |\alpha_i - \beta_{\sigma(i)}|^2 \right)^{1/2} \leq \sqrt{2} \|A - B\|_2.$$

If  $\tau$  is the permutation that realizes the minimum when  $A = X_n$  and  $B = X_n + Y_n$ , and if  $k_n$  is the number of indices  $i \in \{1, \dots, n\}$  such that  $|\lambda_i - \mu_{\tau(i)}| > \varepsilon > 0$ , then

$$\sqrt{k_n} \varepsilon \leq \left( \sum_{i=1}^n |\lambda_i - \mu_{\tau(i)}|^2 \right)^{1/2} \leq \sqrt{2} \|Y_n\|_2 \implies \frac{k_n}{n} \leq 2 \left( \frac{\|Y_n\|_2}{\sqrt{n} \varepsilon} \right)^2 \xrightarrow{n \rightarrow \infty} 0.$$

The last relation implies that

$$d'(\{X_n\}_n, \{X_n + Y_n\}_n) \leq \limsup_{n \rightarrow \infty} \frac{k_n}{n} + \varepsilon = \varepsilon$$

for every  $\varepsilon$ , and Theorem 2.6 allows one to conclude that  $\{X_n + Y_n\}_n \sim_\lambda f$ .  $\square$

**Corollary 2.8.** *Let  $\{X_n\}_n$  be a matrix-sequence such that each  $X_n$  is Hermitian and  $\{X_n\}_n \sim_\lambda f$ , where  $f$  is a measurable function defined on a subset of some  $\mathbb{R}^q$  with finite and positive Lebesgue measure. Suppose that any of the following conditions is met.*

1.  $\|Y_n\|_p = o(\sqrt{n})$  with  $\|\cdot\|_p$  being the Schatten  $p$ -norm for some  $1 \leq p \leq 2$ .
2.  $\|Y_n\| = o(1)$ .

*Then  $\{X_n + Y_n\}_n \sim_\lambda f$ .*

*Proof.* 1. For any matrix  $A$  we have  $\|A\|_p \geq \|A\|_2$  whenever  $1 \leq p \leq 2$ . Hence,

$$\|Y_n\|_p = o(\sqrt{n}) \implies \|Y_n\|_2 = o(\sqrt{n})$$

and the thesis follows from Theorem 1.1.

2. By definition of Schatten 2-norm,

$$\|Y_n\|_2 \leq \sqrt{n} \|Y_n\| = o(\sqrt{n})$$

and the thesis follows from Theorem 1.1.  $\square$

Corollary 2.8 is not a direct generalization of [23, Theorem 3.4], since we changed the perturbation norm from  $\|Y_n\|_1 = o(n)$  to  $\|Y_n\|_1 = o(\sqrt{n})$ . Nevertheless, another corollary of Theorem 1.1 has the same order of perturbation as [23, Theorem 3.4].

**Corollary 2.9.** Let  $\{X_n\}_n$  be a matrix-sequence such that each  $X_n$  is Hermitian and  $\{X_n\}_n \sim_\lambda f$ , where  $f$  is a measurable function defined on a subset of some  $\mathbb{R}^q$  with finite and positive Lebesgue measure. Suppose that both the following conditions are met.

1.  $\|Y_n\|_1 = o(n)$  with  $\|\cdot\|_1$  being the Schatten 1-norm.
2.  $\|Y_n\| = O(1)$ .

Then  $\{X_n + Y_n\}_n \sim_\lambda f$ .

*Proof.* The condition  $\|Y_n\| = O(1)$  ensures the existence of a constant  $C$  such that  $\|Y_n\| < C$  for every  $n$ . If we fix  $\varepsilon > 0$ , we can consider the number  $k_n$  of singular values of  $Y_n$  greater than  $\varepsilon$ . The first condition leads to

$$k_n \varepsilon \leq \|Y_n\|_1 = o(n) \implies k_n = o(n),$$

and therefore

$$\frac{\|Y_n\|_2}{\sqrt{n}} \leq \frac{\sqrt{C^2 k_n + \varepsilon^2 (n - k_n)}}{\sqrt{n}} = \sqrt{(C^2 - 1) \frac{k_n}{n} + \varepsilon^2} = \varepsilon + o(1).$$

The last relation holds for every  $\varepsilon > 0$ , so we can conclude that  $\|Y_n\|_2 = o(\sqrt{n})$  and the thesis follows from Theorem 1.1.  $\square$

### 3 GLT Sequences

Along with the concept of spectral symbol already introduced, we need to recall the notion of *Singular Values Symbol*, that is, a measurable function describing the asymptotic distribution of the singular values of a matrix-sequence. Given  $\{A_n\}_n \in \mathcal{E}$ , a singular value symbol associated with  $\{A_n\}_n$  is a measurable function  $f : D \subseteq \mathbb{R}^q \rightarrow \mathbb{C}$  satisfying

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n F(\sigma_i(A_n)) = \frac{1}{l(D)} \int_D F(|f(x)|) dx$$

for every continuous function  $F : \mathbb{R} \rightarrow \mathbb{C}$  with compact support, where  $D$  is a measurable set with finite Lebesgue measure  $l(D) > 0$  and  $\sigma_i(A_n)$  are the singular values of  $A_n$ . In this case we write

$$\{A_n\}_n \sim_\sigma f.$$

In order to understand the applications that we will present below, we need to introduce a handy tool devised for solving a specific application problem, namely the problem of computing/analysing the spectral distribution of matrices arising from the numerical discretization of integrodifferential equations. It is often observed in practice that matrix-sequences  $\{A_n\}_n$  arising from the discretization of such equations belong to the class of the so-called GLT sequences, and in particular they enjoy an asymptotic singular value and eigenvalue distribution as  $n \rightarrow \infty$ ; we refer the reader to [8] for a nice introduction to this subject and to [1, 18, 19, 20, 21, 30, 31, 33] for more advanced studies. Here we simply summarize the main properties of the theory of GLT sequences, both in the case where the considered integrodifferential equation is univariate and multivariate.

#### 3.1 Unidimensional Case

A GLT sequence  $\{A_n\}_n \in \mathcal{E}$  is a special matrix-sequence equipped with one of its singular values symbols  $\kappa$ , which is referred to as the *GLT Symbol* of  $\{A_n\}_n$  and is defined over the domain  $D = [0, 1] \times [-\pi, \pi]$ . A point of  $D$  is often denoted by  $(x, \theta)$ , and we use the notation  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  to indicate that  $\{A_n\}_n$  is a GLT sequence with symbol  $\kappa$ . The symbol of a GLT sequence is unique in the sense that if  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and  $\{A_n\}_n \sim_{\text{GLT}} \xi$  then  $\kappa = \xi$  almost everywhere (a.e.) in  $[0, 1] \times [-\pi, \pi]$ . The main properties of GLT sequences are summarized below.

**GLT 1.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  then  $\{A_n\}_n \sim_\sigma \kappa$ . If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and each  $A_n$  is Hermitian then  $\{A_n\}_n \sim_\lambda \kappa$ .

**GLT 2.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and  $A_n = X_n + Y_n$ , where

- every  $X_n$  is Hermitian,

- $\|X_n\|, \|Y_n\| \leq C$  for some constant  $C$  independent of  $n$ ,
- $n^{-1}\|Y_n\|_1 \rightarrow 0$ ,

then  $\{A_n\}_n \sim_\lambda \kappa$ .

**GLT 3.** Here we list three fundamental examples of GLT sequences.

- Given a function  $f$  in  $L^1([-\pi, \pi])$ , its associated Toeplitz sequence is  $\{T_n(f)\}_n$ , where

$$T_n(f) = [f_{i-j}]_{i,j=1}^n, \quad f_k = \frac{1}{2\pi} \int_{-\pi}^{\pi} f(\theta) e^{-ik\theta} d\theta.$$

$\{T_n(f)\}_n$  is a GLT sequence with symbol  $\kappa(x, \theta) = f(\theta)$ .

- Given any a.e. continuous function  $a : [0, 1] \rightarrow \mathbb{C}$ , its associated diagonal sampling sequence is  $\{D_n(a)\}_n$ , where

$$D_n(a) = \text{diag}_{i=1, \dots, n} a\left(\frac{i}{n}\right).$$

$\{D_n(a)\}_n$  is a GLT sequence with symbol  $\kappa(x, \theta) = a(x)$ .

- A zero-distributed sequence is a matrix-sequence such that  $\{Z_n\}_n \sim_\sigma 0$ , i.e.,

$$\lim_{n \rightarrow \infty} \frac{1}{n} \sum_{i=1}^n F(\sigma_i(A_n)) = F(0)$$

for every continuous function  $F : \mathbb{R} \rightarrow \mathbb{C}$  with compact support. Any zero-distributed sequence is a GLT sequence with symbol  $\kappa(x, \theta) = 0$ .

**GLT 4.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and  $\{B_n\}_n \sim_{\text{GLT}} \xi$ , then

- $\{A_n^*\}_n \sim_{\text{GLT}} \bar{\kappa}$ , where  $A_n^*$  is the conjugate transpose of  $A_n$ ,
- $\{\alpha A_n + \beta B_n\}_n \sim_{\text{GLT}} \alpha \kappa + \beta \xi$  for all  $\alpha, \beta \in \mathbb{C}$ ,
- $\{A_n B_n\}_n \sim_{\text{GLT}} \kappa \xi$ .

**GLT 5.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and  $\kappa \neq 0$  a.e., then  $\{A_n^\dagger\}_n \sim_{\text{GLT}} \kappa^{-1}$ , where  $A_n^\dagger$  is the Moore–Penrose pseudoinverse of  $A_n$ .

**GLT 6.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and each  $A_n$  is Hermitian, then  $\{f(A_n)\}_n \sim_{\text{GLT}} f(\kappa)$  for all continuous functions  $f : \mathbb{C} \rightarrow \mathbb{C}$ .

**GLT 7.**  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  if and only if there exist GLT sequences  $\{B_{n,m}\}_n \sim_{\text{GLT}} \kappa_m$  such that  $\kappa_m$  converges to  $\kappa$  in measure and  $\{B_{n,m}\}_n \xrightarrow{\text{a.c.s.}} \{A_n\}_n$  as  $m \rightarrow \infty$ .

**GLT 8.** Suppose  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  and  $\{B_{n,m}\}_n \sim_{\text{GLT}} \kappa_m$ , where both  $A_n$  and  $B_{n,m}$  have the same size. Then,  $\{B_{n,m}\}_n \xrightarrow{\text{a.c.s.}} \{A_n\}_n$  as  $m \rightarrow \infty$  if and only if  $\kappa_m$  converges to  $\kappa$  in measure.

**GLT 9.** If  $\{A_n\}_n \sim_{\text{GLT}} \kappa$  then there exist functions  $a_{i,m}, f_{i,m}$ ,  $i = 1, \dots, N_m$ , such that

- $a_{i,m} \in C^\infty([0, 1])$  and  $f_{i,m}$  is a trigonometric polynomial,
- $\sum_{i=1}^{N_m} a_{i,m}(x) f_{i,m}(\theta)$  converges to  $\kappa(x, \theta)$  a.e.,
- $\{\sum_{i=1}^{N_m} D_n(a_{i,m}) T_n(f_{i,m})\}_n \xrightarrow{\text{a.c.s.}} \{A_n\}_n$  as  $m \rightarrow \infty$ .

It will not be necessary to introduce the a.c.s. convergence used in **GLT 7–GLT 9**, but we refer the reader to [29] for the original definition and to [20, Chapter 5] and [1, 3] for a detailed exploration of the topic.

### 3.2 Multidimensional Case

Similarly to the one-dimensional case, a multilevel GLT sequence  $\{A_{\mathbf{n}}\}_n$  is a sequence of matrices with increasing size, equipped with one of its singular values symbols  $\kappa$ , which is referred to as the *GLT Symbol* and is defined over a domain  $D$  of the form  $[0, 1]^d \times [-\pi, \pi]^d$ ,  $d \geq 1$ . A point of  $D = [0, 1]^d \times [-\pi, \pi]^d$  is usually denoted by  $(\mathbf{x}, \boldsymbol{\theta})$ , where  $\mathbf{x} = (x_1, \dots, x_d)$  and  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_d)$  are vectors of variables.

When dealing with multilevel sequences, matrices and vectors, we will use the multi-index notation. A multi-index  $\mathbf{i} \in \mathbb{Z}^d$ , also called a  $d$ -index, is simply a vector in  $\mathbb{Z}^d$ ; its components are denoted by  $i_1, \dots, i_d$ .

- $\mathbf{0}, \mathbf{1}, \mathbf{2}, \dots$  are the vectors of all zeros, all ones, all twos,  $\dots$  (their size will be clear from the context).
- For any  $d$ -index  $\mathbf{m}$ ,  $N(\mathbf{m}) = \prod_{j=1}^d m_j$  and  $\mathbf{m} \rightarrow \infty$  means that  $\min(\mathbf{m}) = \min_{j=1, \dots, d} m_j \rightarrow \infty$ .
- If  $\mathbf{h}, \mathbf{k}$  are  $d$ -indices,  $\mathbf{h} \leq \mathbf{k}$  means that  $h_r \leq k_r$  for all  $r = 1, \dots, d$ , while  $\mathbf{h} \not\leq \mathbf{k}$  means that  $h_r > k_r$  for at least one  $r \in \{1, \dots, d\}$ .
- If  $\mathbf{h}, \mathbf{k}$  are  $d$ -indices such that  $\mathbf{h} \leq \mathbf{k}$ , the multi-index range  $\mathbf{h}, \dots, \mathbf{k}$  is the set  $\{\mathbf{j} \in \mathbb{Z}^d : \mathbf{h} \leq \mathbf{j} \leq \mathbf{k}\}$ . We assume for the multi-index range  $\mathbf{h}, \dots, \mathbf{k}$  the standard lexicographic ordering:

$$\left[ \dots \left[ \left[ (j_1, \dots, j_d) \right]_{j_d=h_d, \dots, k_d} \right]_{j_{d-1}=h_{d-1}, \dots, k_{d-1}} \dots \right]_{j_1=h_1, \dots, k_1}. \quad (5)$$

For instance, in the case  $d = 2$  the ordering is

$$(h_1, h_2), (h_1, h_2 + 1), \dots, (h_1, k_2), (h_1 + 1, h_2), (h_1 + 1, h_2 + 1), \dots, (h_1 + 1, k_2), \\ \dots \dots, (k_1, h_2), (k_1, h_2 + 1), \dots, (k_1, k_2).$$

- When a  $d$ -index  $\mathbf{j}$  varies over a multi-index range  $\mathbf{h}, \dots, \mathbf{k}$  (this is sometimes written as  $\mathbf{j} = \mathbf{h}, \dots, \mathbf{k}$ ), it is understood that  $\mathbf{j}$  varies from  $\mathbf{h}$  to  $\mathbf{k}$  following the specific ordering (5). For instance, if  $\mathbf{m} \in \mathbb{N}^d$  and if we write  $\mathbf{x} = [x_{\mathbf{i}}]_{\mathbf{i}=1}^{\mathbf{m}}$ , then  $\mathbf{x}$  is a vector of size  $N(\mathbf{m})$  whose components  $x_{\mathbf{i}}$ ,  $\mathbf{i} = \mathbf{1}, \dots, \mathbf{m}$ , are ordered in accordance with (5): the first component is  $x_{\mathbf{1}} = x_{(1, \dots, 1, 1)}$ , the second component is  $x_{(1, \dots, 1, 2)}$ , and so on until the last component, which is  $x_{\mathbf{m}} = x_{(m_1, \dots, m_d)}$ . Similarly, if  $X = [x_{\mathbf{i}\mathbf{j}}]_{\mathbf{i}, \mathbf{j}=1}^{\mathbf{m}}$ , then  $X$  is a  $N(\mathbf{m}) \times N(\mathbf{m})$  matrix whose components are indexed by two  $d$ -indices  $\mathbf{i}, \mathbf{j}$ , both varying from  $\mathbf{1}$  to  $\mathbf{m}$  according to the lexicographic ordering (5).
- Operations involving  $d$ -indices that have no meaning in the vector space  $\mathbb{Z}^d$  must always be interpreted in the componentwise sense. For instance,  $\mathbf{i}\mathbf{j} = (i_1 j_1, \dots, i_d j_d)$ ,  $\mathbf{i}/\mathbf{j} = (i_1/j_1, \dots, i_d/j_d)$ , etc.

In this context, by a sequence of matrices (or matrix-sequence) we mean a sequence of the form  $\{A_{\mathbf{n}}\}_n$ , where  $\mathbf{n} = (n_1, \dots, n_d)$  depends on  $n$  and  $\mathbf{n} \rightarrow \infty$  as  $n \rightarrow \infty$ . In many cases, it is natural to assume that  $\mathbf{n} = n\mathbf{c}$ , where  $\mathbf{c}$  is a vector of rational constants and  $n$  diverges to infinity. It is always understood that a matrix  $A_{\mathbf{n}}$  parameterized by a  $d$ -index  $\mathbf{n}$  has dimension  $N(\mathbf{n}) = n_1 \cdots n_d$ ; its entries will be indexed by two  $d$ -indices  $\mathbf{i}, \mathbf{j}$ .

The main theoretical properties of one-dimensional GLT sequences **GLT 1** – **GLT 9** still hold in the multidimensional context, upon substituting the sequences  $\{A_n\}_n$  with the multilevel sequences  $\{A_{\mathbf{n}}\}_n$ . The only exception is **GLT 3**, that has to be rewritten in order to include  $d$ -level Toeplitz matrices generated by a  $d$ -variate function and  $d$ -level diagonal sampling matrices associated with a  $d$ -variate function.

**GLT 3.** Here we list three important examples of GLT sequences.

- Given a function  $f$  in  $L^1([-\pi, \pi]^d)$ , its associated Toeplitz sequence is  $\{T_{\mathbf{n}}(f)\}_n$ , where the elements are multidimensional Fourier coefficients of  $f$ :

$$T_{\mathbf{n}}(f) = [f_{\mathbf{i}-\mathbf{j}}]_{\mathbf{i}, \mathbf{j}=1}^{\mathbf{n}}, \quad f_{\mathbf{k}} = \frac{1}{(2\pi)^d} \int_{-\pi}^{\pi} f(\boldsymbol{\theta}) e^{-i\mathbf{k} \cdot \boldsymbol{\theta}} d\boldsymbol{\theta}.$$

$\{T_{\mathbf{n}}(f)\}_n$  is a GLT sequence with symbol  $\kappa(\mathbf{x}, \boldsymbol{\theta}) = f(\boldsymbol{\theta})$ .

- Given an almost everywhere continuous function,  $a : [0, 1]^d \rightarrow \mathbb{C}$ , its associated diagonal sampling sequence  $\{D_n(a)\}_n$  is defined as

$$D_n(a) = \text{diag} \left( \left\{ a \left( \frac{\mathbf{i}}{n} \right) \right\}_{i=1}^n \right).$$

$\{D_n(a)\}_n$  is a GLT sequence with symbol  $\kappa(\mathbf{x}, \boldsymbol{\theta}) = a(\mathbf{x})$ .

- Any zero-distributed sequence  $\{Z_n\}_n \sim_\sigma 0$  is a GLT sequence with symbol  $\kappa(\mathbf{x}, \boldsymbol{\theta}) = 0$ .

In the next sections we will see examples of matrix-sequences arising from relevant applications in which Theorem 1.1 is essential for deducing the eigenvalue distribution.

## 4 A Few Applications

The section is divided in four subsections. The first two, Subsections 4.1 and 4.2, deal with matrix-sequences coming from the approximation of the same second-order 1D differential equation, by using basic finite differences and linear finite elements, respectively. The last two, Subsections 4.3 and 4.4, are concerned with matrix-sequences coming from the approximation of a  $d$  dimensional PDE and a preconditioning problem, respectively.

### 4.1 Finite Differences: The One-Dimensional Setting

We consider the second-order differential equation with Dirichlet boundary conditions

$$\begin{cases} -(a(x)u'(x))' + b(x)u'(x) + c(x)u(x) = f(x), & x \in (0, 1), \\ u(0) = \alpha, & u(1) = \beta, \end{cases} \quad (6)$$

where

- $a(x), c(x)$  are real-valued function, continuous almost everywhere, defined in  $[0, 1]$ ,
- $b(x)$  is a real-valued function on  $[0, 1]$ , such that  $|b(x)x^\alpha|$  is bounded for some  $\alpha < 3/2$ ,

while  $f(x)$  is a general function. For the GLT analysis presented in this section we do not need further assumptions. We employ central second-order finite differences for approximating the given equation. We define the stepsize  $h = \frac{1}{n+1}$  and the points  $x_k = kh$  for  $k$  belonging to the interval  $[0, n+1]$ . For every  $j = 1, \dots, n$  we have

$$\begin{aligned} -(a(x)u'(x))'|_{x=x_j} &\approx -\frac{a(x_{j+\frac{1}{2}})u'(x_{j+\frac{1}{2}}) - a(x_{j-\frac{1}{2}})u'(x_{j-\frac{1}{2}})}{h} \\ &\approx -\frac{a(x_{j+\frac{1}{2}})\frac{u(x_{j+1})-u(x_j)}{h} - a(x_{j-\frac{1}{2}})\frac{u(x_j)-u(x_{j-1}))}{h}}{h} \\ &= \frac{-a(x_{j+\frac{1}{2}})u(x_{j+1}) + (a(x_{j+\frac{1}{2}}) + a(x_{j-\frac{1}{2}}))u(x_j) - a(x_{j-\frac{1}{2}})u(x_{j-1}))}{h^2} \\ b(x)u'(x)|_{x=x_j} &\approx b(x_j)\frac{u(x_{j+1}) - u(x_{j-1}))}{2h} \\ c(x)u(x)|_{x=x_j} &= c(x_j)u(x_j). \end{aligned}$$

Let  $a_k := a(x_{\frac{k}{2}})$  for any  $k \in [0, 2n+2]$  and set  $b_j := b(x_j)$ ,  $c_j := c(x_j)$ ,  $f_j := f(x_j)$  for every  $j = 0, \dots, n+1$ . We compute approximations  $u_j$  of the values  $u(x_j)$  for  $j = 1, \dots, n$  by solving the following linear system

$$A_n \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_{n-1} \\ u_n \end{pmatrix} + B_n \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_{n-1} \\ u_n \end{pmatrix} + C_n \begin{pmatrix} u_1 \\ u_2 \\ \vdots \\ u_{n-1} \\ u_n \end{pmatrix} = h^2 \begin{pmatrix} f_1 + \frac{1}{h^2}a_1\alpha + \frac{1}{2h}b_1\alpha \\ f_2 \\ \vdots \\ f_{n-1} \\ f_n + \frac{1}{h^2}a_{2n+1}\beta - \frac{1}{2h}b_n\beta \end{pmatrix},$$

where

$$A_n = \begin{pmatrix} a_1 + a_3 & -a_3 & & & & \\ -a_3 & a_3 + a_5 & -a_5 & & & \\ & \ddots & \ddots & \ddots & & \\ & & -a_{2n-3} & a_{2n-3} + a_{2n-1} & -a_{2n-1} & \\ & & & -a_{2n-1} & a_{2n-1} + a_{2n+1} & \end{pmatrix},$$

$$B_n = \frac{h}{2} \begin{pmatrix} 0 & b_1 & & & & \\ -b_2 & 0 & b_2 & & & \\ & \ddots & \ddots & \ddots & & \\ & & -b_{n-1} & 0 & b_{n-1} & \\ & & & -b_n & 0 & \end{pmatrix}, \quad C_n = h^2 \text{diag}(c_1, \dots, c_n).$$

In the case where  $a(x) \equiv 1$  and  $b(x) \equiv 1$ , in accordance with the notation of axiom **GLT 3** in Subsection 3.1, we obtain the basic Toeplitz structures

$$K_n = T_n(2 - 2 \cos(\theta)) = \begin{pmatrix} 2 & -1 & & & \\ -1 & 2 & -1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 2 & -1 \\ & & & -1 & 2 \end{pmatrix}, \quad (7)$$

$$H_n = T_n(i \sin(\theta)) = \frac{1}{2} \begin{pmatrix} 0 & 1 & & & \\ -1 & 0 & 1 & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 0 & 1 \\ & & & -1 & 0 \end{pmatrix}, \quad (8)$$

with  $A_n = K_n$  and  $B_n = hH_n$ . In this case, it is also useful consider the first-order non-central discretization operators, which, after a proper scaling, can be written as

$$K_n^+ = T_n(1 - e^{i\theta}) = \begin{pmatrix} 1 & -1 & & & \\ & 1 & -1 & & \\ & & \ddots & \ddots & \\ & & & 1 & -1 \\ & & & & 1 \end{pmatrix},$$

$$K_n^- = T_n(1 - e^{-i\theta}) = \begin{pmatrix} 1 & & & & \\ -1 & 1 & & & \\ & \ddots & \ddots & \ddots & \\ & & -1 & 1 & \\ & & & -1 & 1 \end{pmatrix}. \quad (9)$$

By setting

$$D_n^+(a) := \text{diag}(a_3, a_5, \dots, a_{2n+1}), \quad D_n^-(a) := \text{diag}(a_1, a_3, \dots, a_{2n-1}),$$

the matrix-sequences  $\{D_n^+(a)\}_n$  and  $\{D_n^-(a)\}_n$  are GLT sequences with symbol  $a(x)$  and the proof is virtually identical to that for showing  $\{D_n(a)\}_n \sim_{\text{GLT}} a(x)$  (see [20]). As a consequence of the algebra structure of GLT sequences, that is, using axioms **GLT 3** and **GLT 4**, we obtain

$$A_n = D_n^+(a)K_n^+ + D_n^-(a)K_n^- \implies \{A_n\}_n \sim_{\text{GLT}} a(x)(2 - 2 \cos(\theta)).$$

Furthermore, regarding the matrices  $C_n$ , we have

$$\{D_n(c)\}_n \sim_{\text{GLT}} c(x) \quad \{n^{-2}I_n\}_n \sim_{\text{GLT}} 0 \implies \{C_n\}_n = \{n^{-2}D_n(c)\}_n \sim_{\text{GLT}} 0,$$

which, again by axioms **GLT 3** and **GLT 4**, implies that  $\{A_n\}_n + \{C_n\}_n \sim_{\text{GLT}} a(x)(2 - 2\cos(\theta))$ . By exploiting the real symmetry of all the considered matrices and in view of axiom **GLT 1**, we obtain

$$\{A_n\}_n + \{C_n\}_n \sim_{\lambda} a(x)(2 - 2\cos(\theta)).$$

For the matrices  $B_n$ , taking into account Theorem 1.1, we are interested in estimating their Schatten 2-norm (Frobenius norm in the numerical analysis community). Suppose that there exists a constant  $C > 0$  such that  $|b(x)x^\alpha| < C$ . If  $\alpha < 1$ , then  $|b(x)x| \leq |b(x)x^\alpha| < C$ , so we analyse only the case  $\alpha \geq 1$ . We have

$$\|B_n\|_2^2 \leq \frac{h^2}{2} \sum_{i=1}^n b_i^2 = \frac{h^2}{2} \sum_{i=1}^n b(ih)^2 \leq \frac{C^2 h^2}{2} \sum_{i=1}^n (ih)^{-2\alpha} = \frac{C^2 h^{2-2\alpha}}{2} \sum_{i=1}^n i^{-2\alpha}. \quad (10)$$

Since  $-2\alpha \leq -2$ , we can estimate the last sum with the integral of  $x^{2\alpha+1}$ , in the following way

$$\sum_{i=1}^n i^{-2\alpha} \leq 1 + \int_1^n x^{-2\alpha} dx = \frac{2\alpha - n^{-2\alpha+1}}{2\alpha - 1}. \quad (11)$$

Substituting (11) into (10), we obtain

$$\|B_n\|_2^2 \leq \frac{C^2 h^{2-2\alpha}}{2} \sum_{i=1}^n i^{-2\alpha} \leq \frac{C^2 \alpha}{2\alpha - 1} h^{2-2\alpha} - \frac{C^2}{4\alpha - 2} h,$$

which implies

$$\|B_n\|_2 = O(n^{\alpha-1}). \quad (12)$$

Observe that  $\frac{3}{2} > \alpha$  leads to  $\|B_n\|_2 = o(\sqrt{n})$ . By invoking Theorem 1.1, we simply conclude

$$\{A_n\}_n + \{B_n\}_n + \{C_n\}_n \sim_{\lambda} a(x)(2 - 2\cos(\theta)),$$

with  $\{X_n\}_n = \{A_n\}_n + \{C_n\}_n$ ,  $\{Y_n\}_n = \{B_n\}_n$ , and where the matrix-sequence  $\{B_n\}_n$  is non-symmetric.

## 4.2 Finite Elements: The One-Dimensional Setting

Let us consider the same equation as in the previous subsection, but with slightly different conditions on the variable coefficients

$$\begin{cases} -(a(x)u'(x))' + b(x)u'(x) + c(x)u(x) = f(x), & x \in (0, 1), \\ u(0) = 0, & u(1) = 0. \end{cases}$$

Here we assume  $a(x), b(x), c(x)$  simply Lebesgue integrable, while  $f(x)$  is a general function. We write it in weak form

$$\begin{cases} \int_0^1 a(x)u'(x)w'(x) + b(x)u'(x)w(x) + c(x)u(x)w(x)dx = \int_0^1 f(x)w(x)dx, & x \in (0, 1), \\ u(0) = 0, & u(1) = 0, \end{cases}$$

where  $w(x)$  is allowed to belong to the Sobolev space  $H_0^1([0, 1])$ . We set  $h = \frac{1}{n+1}$  and  $x_k = kh$  for  $k$  integer in the interval  $[0, n+1]$ . We consider the so-called hat functions

$$\varphi_{i,n}(x) = \frac{1}{h} [(x - x_{i-1})\chi_{[x_{i-1}, x_i]}(x) + (x_{i+1} - x)\chi_{[x_i, x_{i+1}]}(x)], \quad i = 1, \dots, n,$$

and assume that the functions  $u(x)$  and  $w(x)$  belong to the linear space spanned by  $\varphi_i(x)$ , that is,

$$u(x) = \sum_{j=1}^n u_{j,n} \varphi_{j,n}(x), \quad w(x) = \sum_{i=1}^n w_{i,n} \varphi_{i,n}(x).$$

By substituting these expressions in the weak form, we obtain that the integral

$$\int_0^1 a(x)u'(x)w'(x) + b(x)u'(x)w(x) + c(x)u(x)w(x)dx$$

is equal to

$$\begin{aligned} & \sum_{i,j=1}^n u_{j,n} w_{i,n} \int_0^1 a(x) \varphi'_{i,n}(x) \varphi'_{j,n}(x) dx + \sum_{i,j=1}^n u_{j,n} w_{i,n} \int_0^1 b(x) \varphi_{i,n}(x) \varphi'_{j,n}(x) dx \\ & + \sum_{i,j=1}^n u_{j,n} w_{i,n} \int_0^1 c(x) \varphi_{i,n}(x) \varphi_{j,n}(x) dx, \end{aligned}$$

while

$$\int_0^1 f(x) w(x) dx = \sum_{j=1}^n w_{i,n} \int_0^1 f(x) \varphi_{i,n}(x) dx.$$

Therefore, if  $u^n$  denotes the vector of the unknowns  $u_{i,n}$ ,  $w^n$  the vector of the values  $w_{i,n}$ , and

$$\begin{aligned} A_n &= \left( \int_0^1 a(x) \varphi'_{i,n}(x) \varphi'_{j,n}(x) dx \right)_{i,j}, \\ B_n &= \left( \int_0^1 b(x) \varphi_{i,n}(x) \varphi'_{j,n}(x) dx \right)_{i,j}, \\ C_n &= \left( \int_0^1 c(x) \varphi_{i,n}(x) \varphi_{j,n}(x) dx \right)_{i,j}, \\ f^n &= \left( \int_0^1 f(x) \varphi_{i,n}(x) dx \right)_i, \end{aligned}$$

we deduce that the relationships

$$(w^n)^T (A_n + B_n + C_n) u^n = (w^n)^T f^n$$

have to be satisfied for every  $w^n$ . The latter is clearly equivalent to the linear system

$$(A_n + B_n + C_n) u^n = f^n.$$

We notice that

$$\int_0^1 a(x) \varphi'_{i,n}(x) \varphi'_{j,n}(x) dx = (n+1)^2 \begin{cases} 0 & |i-j| > 1 \\ -\int_{x_i}^{x_{i+1}} a(x) dx & j = i+1 \\ -\int_{x_{i-1}}^{x_i} a(x) dx & i = j+1 \\ \int_{x_{i-1}}^{x_{i+1}} a(x) dx & i = j \end{cases}$$

$$\int_0^1 b(x) \varphi_{i,n}(x) \varphi'_{j,n}(x) dx = (n+1) \begin{cases} 0 & |i-j| > 1 \\ -\int_{x_{i-1}}^{x_i} b(x) \varphi_{i,n}(x) dx & i = j+1 \\ \int_{x_i}^{x_{i+1}} b(x) \varphi_{i,n}(x) dx & j = i+1 \\ \int_{x_{i-1}}^{x_i} b(x) \varphi_{i,n}(x) dx - \int_{x_i}^{x_{i+1}} b(x) \varphi_{i,n}(x) dx & i = j \end{cases}$$

The matrices  $A_n$  are all real symmetric and, according to [20][Exercise 10.4], we already know that

$$\left\{ \frac{1}{n+1} A_n \right\}_n \sim_{\text{GLT}} a(x) (2 - 2 \cos(\theta)).$$

Let us compute the Schatten 2-norm of  $B_n$ :

$$\begin{aligned}
\frac{1}{n+1}\|B_n\|_2 &= \frac{1}{n+1}\sqrt{\sum_{i,j=1}^n (B_n)_{i,j}^2} \leq \frac{1}{n+1}\sum_{i,j=1}^n |(B_n)_{i,j}| \\
&= \sum_{i=1}^{n-1}\left|\int_{x_i}^{x_{i+1}} b(x)\varphi_{i,n}(x)dx\right| + \sum_{i=2}^n\left|\int_{x_{i-1}}^{x_i} b(x)\varphi_{i,n}(x)dx\right| \\
&\quad + \sum_{i=1}^n\left|\int_{x_{i-1}}^{x_i} b(x)\varphi_{i,n}(x)dx - \int_{x_i}^{x_{i+1}} b(x)\varphi_{i,n}(x)dx\right| \\
&\leq \int_{x_0}^{x_1} |b(x)|\varphi_{1,n}(x)dx + \int_{x_n}^{x_{n+1}} |b(x)|\varphi_{n,n}(x)dx \\
&\quad + \sum_{i=1}^{n-1}\int_{x_i}^{x_{i+1}} 2|b(x)|(\varphi_{i+1,n}(x) + \varphi_{i,n}(x))dx \\
&\leq 2\sum_{i=0}^n\int_{x_i}^{x_{i+1}} |b(x)|dx = 2\|b(x)\|_1. \tag{13}
\end{aligned}$$

From the inequalities above we have

$$\left\|\frac{1}{n+1}B_n\right\|_2 = o(\sqrt{n}).$$

A similar derivation can be performed for  $C_n$  and the conclusion is that

$$\|C_n\|_2 \leq \sum_{i,j=1}^n |(C_n)_{i,j}| \leq \sum_{|i-j|<2} \int_0^1 |c(x)|\varphi_{i,n}(x)\varphi_{j,n}(x)dx \leq 3n\|c(x)\|_1,$$

hence

$$\left\|\frac{1}{n+1}C_n\right\|_2 \leq \|c(x)\|_1 = O(1).$$

This leads to the conclusion

$$\left\{\frac{1}{n+1}C_n\right\}_n \sim_\sigma 0,$$

which is equivalent to  $\{\frac{1}{n+1}C_n\}_n \sim_{\text{GLT}} 0$  by axiom **GLT 4**. By axiom **GLT 4** we have

$$\left\{\frac{1}{n+1}(A_n + C_n)\right\}_n \sim_{\text{GLT}} a(x)(2 - 2\cos(\theta))$$

and hence

$$\left\{\frac{1}{n+1}(A_n + C_n)\right\}_n \sim_\lambda a(x)(2 - 2\cos(\theta))$$

by axiom **GLT 1** and the real symmetry of all the involved matrices (see again [20][Exercise 10.4]). In conclusion, by applying Theorem 1.1 with  $\{X_n\}_n = \{\frac{1}{n+1}(A_n + C_n)\}_n$  and  $\{Y_n\}_n = \{\frac{1}{n+1}B_n\}_n$ , we deduce the spectral distribution of the complete (nonsymmetric) matrix-sequence, that is,

$$\left\{\frac{1}{n+1}A_n\right\}_n + \left\{\frac{1}{n+1}B_n\right\}_n + \left\{\frac{1}{n+1}C_n\right\}_n \sim_\lambda a(x)(2 - 2\cos(\theta)).$$

#### 4.2.1 Minimal Hypothesis

In the previous section, we actually proved that  $\frac{1}{n+1}\|B_n\|_2 = O(1)$ , so we still have to exploit the full power of Theorem 1.1. Suppose that  $b(x)$  is a function on  $[0, 1]$  with a single discontinuity point in zero of order  $\alpha$ , in the sense that

$$|b(x)x^{-\alpha}| \leq C, \quad \forall x > 0,$$

where  $C > 0$  is a constant. To ensure that the matrix  $B_n$  is well defined, we have to check at least that every elements is finite. In the case  $\alpha > -2$  we have

$$\left| \int_{x_0}^{x_1} \varphi_1(x)b(x) \right| \leq C \int_{x_0}^{x_1} \varphi_{1,n}(x)x^\alpha dx = \frac{C}{h} \int_0^h x^{\alpha+1} dx < \infty.$$

As a consequence, if  $\alpha > -2$  then the matrices  $B_n$  are well defined; and if  $\alpha > -1$  then the function  $|b(x)|$  belongs to  $L^1(0, 1)$  and this case has already been addressed above. Here we want to explore the case  $-2 < \alpha < -1$ . With reference to the chain of equalities and inequalities in (13), we have

$$\begin{aligned} \frac{1}{n+1} \|B_n\|_2 &\leq \int_{x_0}^{x_1} |b(x)|\varphi_{1,n}(x)dx + \int_{x_n}^{x_{n+1}} |b(x)|\varphi_{n,n}(x)dx \\ &\quad + \sum_{i=1}^{n-1} \int_{x_i}^{x_{i+1}} 2|b(x)|(\varphi_{i+1,n}(x) + \varphi_{i,n}(x))dx \\ &\leq \int_{x_0}^{x_1} |b(x)|\varphi_{1,n}(x)dx + 2 \int_{x_1}^{x_{n+1}} |b(x)|dx \\ &\leq \frac{C}{h} \int_0^h x^{\alpha+1} dx + 2C \int_h^1 x^\alpha dx = O(n^{-\alpha-1}). \end{aligned} \tag{14}$$

With the same computation, it is easy to show that if  $\alpha = -1$  then  $\frac{1}{n+1} \|B_n\|_2 = O(\log(n))$ . Observe that  $-\frac{3}{2} < \alpha$  leads to  $\frac{1}{n+1} \|B_n\|_2 = o(\sqrt{n})$  and therefore, by Theorem 1.1, we conclude again that

$$\left\{ \frac{1}{n+1} A_n \right\}_n + \left\{ \frac{1}{n+1} B_n \right\}_n + \left\{ \frac{1}{n+1} C_n \right\}_n \sim_\lambda a(x)(2 - 2 \cos(\theta)).$$

### 4.3 Finite Differences: A General Second-Order approximated PDE in $d$ dimensions

In this subsection we extend to the  $d$ -dimensional setting the study carried out in Subsection 4.1 and we indicate a general framework for treating  $d$ -dimensional problems, including also a general recipe for extending the results of Subsection 4.2. One of the main contributions relies on the statement that no substantial difference is encountered when passing from 1 to  $d$  space dimensions. Of course, the  $d$ -dimensional GLT analysis involves several technicalities, but it is conceptually identical to the one-dimensional GLT analysis. The most important technicality which is encountered when passing from 1 to  $d$  space dimensions is the *multi-index language*, which allows one to maintain the 1D notation by simply turning some letters ( $n, i, j$ , etc.) in boldface ( $\mathbf{n}, \mathbf{i}, \mathbf{j}$ , etc.).

Before starting, let us outline the main general ideas of a  $d$ -dimensional GLT analysis. Consider for example a linear second-order PDE such as

$$\begin{cases} -\nabla \cdot \mathbf{A} \nabla u + \mathbf{b} \cdot \nabla u + cu = f, & \text{in } (0, 1)^d, \\ u = 0, & \text{on } \partial((0, 1)^d), \end{cases} \tag{15}$$

where  $\mathbf{A} : [0, 1]^d \rightarrow \mathbb{R}^{d \times d}$  is a symmetric matrix of functions  $a_{hk}$ . As in the 1-dimensional case, we should assume at least  $a_{hk} \in C^1([0, 1]^d)$  to ensure the well-posedness of problem (15), but for the analysis we only need the weaker condition that  $a_{hk}$  are continuous a.e. on  $[0, 1]^d$ .  $\mathbf{b} : [0, 1]^d \rightarrow \mathbb{R}^d$  is a vector of real-valued functions  $b_k(\mathbf{x})$  on  $[0, 1]^d$  such that  $|b_k(\mathbf{x})(x_1 \cdots x_d)^\alpha|$  is bounded by the same constant for all indices  $k$  for some exponent  $\frac{1}{d} + \frac{1}{2} > \alpha$ . We also require that  $c$  is a real-valued a.e. continuous function on  $[0, 1]^d$ . We now observe that (15) is equivalent to

$$\begin{cases} - \sum_{h,k=1}^d \frac{\partial}{\partial x_h} \left( a_{hk} \frac{\partial u}{\partial x_k} \right) + \sum_{k=1}^d b_k \frac{\partial u}{\partial x_k} + cu = f, & \text{in } (0, 1)^d, \\ u = 0, & \text{on } \partial((0, 1)^d). \end{cases} \tag{16}$$

Assume we discretize (16) by a local method; to fix the ideas, here we will assume that such method is a finite difference (FD) scheme. The resulting discretization matrices  $A_n$  are parametrized by a multi-index  $\mathbf{n} = (n_1, \dots, n_d)$ , where  $n_i$  is related to the discretization step  $h_i$  in the  $i$ th direction, and  $n_i \rightarrow \infty$  if and only if  $h_i \rightarrow 0$  (usually,  $h_i \sim 1/n_i$ ). By choosing  $n_i = n$  for some  $n \in \mathbb{N}$  — as it often happens in practice — we see that  $\mathbf{n} = (n, \dots, n)$

and, consequently,  $\{A_{\mathbf{n}}\}_n$  is a matrix-sequence. The matrix  $A_{\mathbf{n}}$  can be decomposed according to the terms of the PDE as follows:

$$A_{\mathbf{n}} = \sum_{h,k=1}^d K_{\mathbf{n},hk}(a_{hk}) + \sum_{k=1}^d H_{\mathbf{n},k}(b_k) + I_{\mathbf{n}}(c)$$

where  $K_{\mathbf{n},hk}(a)$ ,  $H_{\mathbf{n},k}(b)$  and  $I_{\mathbf{n}}(c)$  are the matrices resulting from the considered FD discretization of the differential operators

$$-\frac{\partial}{\partial x_h} \left( a \frac{\partial u}{\partial x_k} \right), \quad b \frac{\partial u}{\partial x_k}, \quad cu,$$

respectively. It usually turns out that, after a suitable normalization that we ignore in this discussion, the matrix-sequence  $\{H_{\mathbf{n},k}(b) + I_{\mathbf{n}}(c)\}_n$  associated with the lower-order differential operators of the PDE (16) is zero-distributed and the GLT analysis of  $\{A_{\mathbf{n}}\}_n$  reduces to the GLT analysis of the matrix-sequence

$$\left\{ \sum_{h,k=1}^d K_{\mathbf{n},hk}(a_{hk}) \right\}_n$$

associated with the higher-order differential operator of the PDE (16). Moreover, the sequences  $\{K_{\mathbf{n},hk}(a_{hk})\}_n$  often turns out to be GLT sequences of the form

$$K_{\mathbf{n},hk}(a_{hk}) = D_{\mathbf{n}}(a_{hk})T_{\mathbf{n}}(p_{hk}) + Z_{\mathbf{n},hk}, \quad \{Z_{\mathbf{n},hk}\}_n \sim_{\sigma} 0,$$

where  $p_{hk}$  is the (separable) trigonometric polynomial that represents the FD formula used to discretize the derivative  $-\frac{\partial^2 u}{\partial x_h \partial x_k}$ . In conclusion we have

$$\{K_{\mathbf{n},hk}\}_n \sim_{\text{GLT}} a_{hk}(\mathbf{x})p_{hk}(\boldsymbol{\theta}) \quad (17)$$

and, consequently,

$$\{A_{\mathbf{n}}\}_n \sim_{\text{GLT}} \sum_{h,k=1}^d a_{hk}(\mathbf{x})p_{hk}(\boldsymbol{\theta}) = \mathbf{1}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\mathbf{1}^T, \quad (18)$$

where

$$H_{hk} = p_{hk}, \quad h, k = 1, \dots, d.$$

From (18) and Theorem 1.1, we arrive at the distribution relation

$$\{A_{\mathbf{n}}\}_n \sim_{\lambda} \sum_{h,k=1}^d a_{hk}(\mathbf{x})p_{hk}(\boldsymbol{\theta}) = \mathbf{1}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\mathbf{1}^T.$$

In particular, with respect to the original result by Golinskii and the second author [23, Theorem 3.4], Theorem 1.1 allows us to relax the assumptions on  $A(\mathbf{x})$  under which the previous relation holds. More specifically, the coefficients of  $A(\mathbf{x})$  can now be supposed to be unbounded.

We note the formal analogy between the expression of the symbol  $\mathbf{1}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\mathbf{1}^T$  and the expression of the higher-order differential operator  $\mathbf{1}(A \circ Hu)\mathbf{1}^T$  in (16). Because of this analogy, and especially because of (17), the matrix  $H(\boldsymbol{\theta})$  in the Fourier variables  $\boldsymbol{\theta}$  is usually referred to as the ‘symbol of the (negative) Hessian operator’, although this terminology is clearly not rigorous from the mathematical viewpoint. If we change the FD formulas to discretize the derivative  $-\frac{\partial^2 u}{\partial x_h \partial x_k}$ , the symbol remains the same except for the matrix  $H(\boldsymbol{\theta})$ , which now collects the (separable) trigonometric polynomials associated with the new FD formulas — or with the ‘formulas’ associated with the considered local method, which may be for example the finite element (FE) method or the isogeometric analysis (IgA); the only possible difference when passing from FDs to other local methods consists in the choice of the proper scaling, which depends only on the fact that either a Galerkin method (FEs, Galerkin IgA, etc.) or a collocation method (FDs, collocation IgA, etc.) is used. This discussion motivates why we do not generalize explicitly the analysis in Subsection 4.2: it would be a plain combination of the analysis for finite elements in one dimension and the analysis in the present subsection.

### 4.3.1 FD discretization of convection-diffusion-reaction equations

We consider the classical central FD discretizations of (16). We choose  $\mathbf{n} \in \mathbb{N}^d$  and we set  $\mathbf{h} = \frac{\mathbf{1}}{\mathbf{n}+1}$  and  $x_j = \mathbf{j}\mathbf{h}$  for  $\mathbf{j} = \mathbf{0}, \dots, \mathbf{n} + \mathbf{1}$ .<sup>1</sup> Let  $\mathbf{e}_k$  be the  $k$ th vector of the canonical basis of  $\mathbb{R}^d$  and notice that  $x_j + sh_k\mathbf{e}_k = x_{j+s\mathbf{e}_k}$ . Then, for  $\mathbf{j} = \mathbf{1}, \dots, \mathbf{n}$ , we can approximate the terms appearing in (16) as follows:

$$\begin{aligned} \frac{\partial}{\partial x_k} \left( a_{kk} \frac{\partial u}{\partial x_k} \right) \Big|_{x=x_j} &\approx \frac{a_{kk} \frac{\partial u}{\partial x_k}(x_{j+\mathbf{e}_k/2}) - a_{kk} \frac{\partial u}{\partial x_k}(x_{j-\mathbf{e}_k/2})}{h_k} \\ &\approx a_{kk}(x_{j+\mathbf{e}_k/2}) \frac{u(x_{j+\mathbf{e}_k}) - u(x_j)}{h_k^2} - a_{kk}(x_{j-\mathbf{e}_k/2}) \frac{u(x_j) - u(x_{j-\mathbf{e}_k})}{h_k^2} \end{aligned} \quad (19)$$

$$\begin{aligned} \frac{\partial}{\partial x_h} \left( a_{hk} \frac{\partial u}{\partial x_k} \right) \Big|_{x=x_j} &\approx \frac{a_{hk} \frac{\partial u}{\partial x_k}(x_{j+\mathbf{e}_h}) - a_{hk} \frac{\partial u}{\partial x_k}(x_{j-\mathbf{e}_h})}{2h_h} \\ &\approx a_{hk}(x_{j+\mathbf{e}_h}) \frac{u(x_{j+\mathbf{e}_h+\mathbf{e}_k}) - u(x_{j+\mathbf{e}_h-\mathbf{e}_k})}{4h_h h_k} - a_{hk}(x_{j-\mathbf{e}_h}) \frac{u(x_{j-\mathbf{e}_h+\mathbf{e}_k}) - u(x_{j-\mathbf{e}_h-\mathbf{e}_k})}{4h_h h_k} \end{aligned} \quad (20)$$

$$b_k \frac{\partial u}{\partial x_k} \Big|_{x=x_j} \approx b_k(x_j) \frac{u(x_{j+\mathbf{e}_k}) - u(x_{j-\mathbf{e}_k})}{2h_k}, \quad (21)$$

$$cu|_{x=x_j} = c(x_j)u(x_j), \quad (22)$$

for  $h, k = 1, \dots, d$ ,  $h \neq k$ . The evaluations  $u(x_j)$  of the solution of (16) at the grid points  $x_j$  are approximated by the values  $u_j$ , where  $u_j = 0$  for  $\mathbf{j} \in \{\mathbf{0}, \dots, \mathbf{n} + \mathbf{1}\} \setminus \{\mathbf{1}, \dots, \mathbf{n}\}$ , and the vector  $\mathbf{u} = (u_1, \dots, u_n)^T$  is the solution of the linear system

$$\begin{aligned} & - \sum_{k=1}^d a_{kk}(x_{j+\mathbf{e}_k/2}) \frac{u_{j+\mathbf{e}_k} - u_j}{h_k^2} - a_{kk}(x_{j-\mathbf{e}_k/2}) \frac{u_j - u_{j-\mathbf{e}_k}}{h_k^2} \\ & - \sum_{\substack{h,k=1 \\ h \neq k}}^d a_{hk}(x_{j+\mathbf{e}_h}) \frac{u_{j+\mathbf{e}_h+\mathbf{e}_k} - u_{j+\mathbf{e}_h-\mathbf{e}_k}}{4h_h h_k} - a_{hk}(x_{j-\mathbf{e}_h}) \frac{u_{j-\mathbf{e}_h+\mathbf{e}_k} - u_{j-\mathbf{e}_h-\mathbf{e}_k}}{4h_h h_k} \\ & + \sum_{k=1}^d b_k(x_j) \frac{u_{j+\mathbf{e}_k} - u_{j-\mathbf{e}_k}}{2h_k} + c(x_j)u_j = f(x_j), \quad \mathbf{j} = \mathbf{1}, \dots, \mathbf{n}. \end{aligned} \quad (23)$$

We now want to understand the structure of the matrix  $A_{\mathbf{n}}$  associated with the linear system (23). This is clearly important for the GLT analysis of the next paragraph. Luckily, the multi-index language allows us to provide a compact and easy-to-manage expression of this matrix. First of all, we note that  $A_{\mathbf{n}}$  admits the following natural

<sup>1</sup>Operations involving  $d$ -indices in  $\mathbb{Z}^d$  must be interpreted in the componentwise sense. In the present case, given  $\mathbf{n} = (n_1, \dots, n_d)$ , the vector of discretization steps  $\mathbf{h} = \frac{\mathbf{1}}{\mathbf{n}+1}$  and the grid points  $x_j = \mathbf{j}\mathbf{h}$  are given by  $\mathbf{h} = \left( \frac{1}{n_1+1}, \dots, \frac{1}{n_d+1} \right) = (h_1, \dots, h_d)$  and  $x_j = (j_1 h_1, \dots, j_d h_d)$ .

decomposition:

$$\begin{aligned}
A_{\mathbf{n}} &= \sum_{k=1}^d \frac{1}{h_k^2} \left( \text{diag}_{j=1, \dots, \mathbf{n}} a_{kk}(x_{j+\mathbf{e}_k/2}) \right) K_{\mathbf{n},kk}^+ \\
&+ \sum_{k=1}^d \frac{1}{h_k^2} \left( \text{diag}_{j=1, \dots, \mathbf{n}} a_{kk}(x_{j-\mathbf{e}_k/2}) \right) K_{\mathbf{n},kk}^- \\
&+ \sum_{\substack{h,k=1 \\ h \neq k}}^d \frac{1}{h_h h_k} \left( \text{diag}_{j=1, \dots, \mathbf{n}} a_{hk}(x_{j+\mathbf{e}_h}) \right) K_{\mathbf{n},hk}^+ \\
&+ \sum_{\substack{h,k=1 \\ h \neq k}}^d \frac{1}{h_h h_k} \left( \text{diag}_{j=1, \dots, \mathbf{n}} a_{hk}(x_{j-\mathbf{e}_h}) \right) K_{\mathbf{n},hk}^- \\
&+ \sum_{k=1}^d \frac{1}{h_k} \left( \text{diag}_{j=1, \dots, \mathbf{n}} b_k(x_j) \right) H_{\mathbf{n},k} + \left( \text{diag}_{j=1, \dots, \mathbf{n}} c(x_j) \right),
\end{aligned} \tag{24}$$

where the matrices  $K_{\mathbf{n},hk}^{\pm}$  and  $H_{\mathbf{n},k}$  are defined by their action on a generic vector  $\mathbf{u} \in \mathbb{R}^{N(\mathbf{n})}$ , as follows:

$$(K_{\mathbf{n},kk}^{\pm} \mathbf{u})_j = u_j - u_{j \pm \mathbf{e}_k}, \tag{25}$$

$$(K_{\mathbf{n},hk}^{\pm} \mathbf{u})_j = \frac{u_{j \pm (\mathbf{e}_h - \mathbf{e}_k)} - u_{j \pm (\mathbf{e}_h + \mathbf{e}_k)}}{4}, \tag{26}$$

$$(H_{\mathbf{n},k} \mathbf{u})_j = \frac{1}{2}(-u_{j-\mathbf{e}_k} + u_{j+\mathbf{e}_k}), \tag{27}$$

$j = 1, \dots, \mathbf{n}$ ,  $k, h = 1, \dots, d$ ,  $h \neq k$  (it is understood that  $u_i = 0$  whenever  $i \notin \{1, \dots, \mathbf{n}\}$ ). Using the multi-index language, it is not difficult to see that

$$K_{\mathbf{n},kk}^{\pm} = \left( \bigotimes_{r=1}^{k-1} I_{n_r} \right) \otimes K_{n_k}^{\pm} \otimes \left( \bigotimes_{r=k+1}^d I_{n_r} \right), \quad k = 1, \dots, d, \tag{28}$$

$$K_{\mathbf{n},hk}^{\pm} = \mp \frac{1}{2} \left( \bigotimes_{r=1}^{h-1} I_{n_r} \right) \otimes J_{n_h}^{\pm} \otimes \left( \bigotimes_{r=h+1}^{k-1} I_{n_r} \right) \otimes H_{n_k} \otimes \left( \bigotimes_{r=k+1}^d I_{n_r} \right), \quad 1 \leq h \neq k \leq d, \tag{29}$$

$$H_{\mathbf{n},k} = \left( \bigotimes_{r=1}^{k-1} I_{n_r} \right) \otimes H_{n_k} \otimes \left( \bigotimes_{r=k+1}^d I_{n_r} \right), \quad k = 1, \dots, d, \tag{30}$$

where  $K_n^{\pm}$ ,  $H_n$  (see (8) and (9)),  $I_n$  are the matrices associated with the first-order FD discretizations of constant-coefficient 1D diffusion equations and  $J_n^{\pm}$  are the  $n \times n$  Jordan nilpotent matrices

$$J_n^{\pm} = I_n - K_n^{\pm}.$$

Since  $K_n^{\pm} = T_n(1 - e^{\pm i\theta})$ ,  $H_n = i T_n(\sin \theta)$  and  $J_n^{\pm} = T_n(e^{\pm i\theta})$ , from (28)–(30) and the relation

$$T_{n_1}(f_1) \otimes \dots \otimes T_{n_d}(f_d) = T_{\mathbf{n}}(f_1 \otimes \dots \otimes f_d),$$

we deduce that

$$K_{\mathbf{n},kk}^{\pm} = T_{\mathbf{n}}(1 - e^{\pm i\theta_k}), \quad k = 1, \dots, d, \tag{31}$$

$$K_{\mathbf{n},hk}^{\pm} = \mp \frac{i}{2} T_{\mathbf{n}}(e^{\pm i\theta_h} \sin \theta_k), \quad 1 \leq h \neq k \leq d, \tag{32}$$

$$H_{\mathbf{n},k} = i T_{\mathbf{n}}(\sin \theta_k), \quad k = 1, \dots, d, \tag{33}$$

and in particular,

$$K_{\mathbf{n},kk}^+ + K_{\mathbf{n},kk}^- = T_{\mathbf{n}}(2 - 2 \cos \theta_k), \quad k = 1, \dots, d, \quad (34)$$

$$K_{\mathbf{n},hk}^+ + K_{\mathbf{n},hk}^- = T_{\mathbf{n}}(\sin \theta_h \sin \theta_k), \quad 1 \leq h \neq k \leq d. \quad (35)$$

If  $H : [0, 1]^d \rightarrow \mathbb{R}^{d \times d}$  is the symmetric matrix of continuous functions defined by

$$(H(\boldsymbol{\theta}))_{kk} = 2 - 2 \cos \theta_k, \quad k = 1, \dots, d, \quad (36)$$

$$(H(\boldsymbol{\theta}))_{hk} = \sin \theta_h \sin \theta_k, \quad 1 \leq h \neq k \leq d, \quad (37)$$

we prove

$$\{n^{-2} A_{\mathbf{n}}\}_n \sim_{\text{GLT}} f^{(\boldsymbol{\nu})}, \quad (38)$$

$$\{n^{-2} A_{\mathbf{n}}\}_n \sim_{\sigma, \lambda} f^{(\boldsymbol{\nu})}, \quad (39)$$

where

$$f^{(\boldsymbol{\nu})}(\mathbf{x}, \boldsymbol{\theta}) = \boldsymbol{\nu}(\mathbf{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T = \sum_{h,k=1}^d \nu_h \nu_k a_{hk}(\mathbf{x})(H(\boldsymbol{\theta}))_{hk}. \quad (40)$$

Despite the technicalities intrinsic to any  $d$ -dimensional analysis, the proof of (38)–(39) is essentially the same as in the 1-dimensional case. It consists of the following steps. Throughout this proof,  $C$  denotes a generic constant independent of  $n$ . From now on, we assume to have a single discretization parameter  $n$  which varies in the infinite set of indices such that  $\mathbf{n} + \mathbf{1} = \boldsymbol{\nu}n \in \mathbb{N}^d$ , where  $\boldsymbol{\nu} = (\nu_1, \dots, \nu_d) \in \mathbb{Q}^d$  is an a priori fixed vector with positive components. The relation  $\mathbf{n} + \mathbf{1} = \boldsymbol{\nu}n$  should be kept in mind while reading the proof.

*Step 1.* Decompose  $A_{\mathbf{n}}$  as follows:

$$A_{\mathbf{n}} = K_{\mathbf{n}} + B_{\mathbf{n}} + C_{\mathbf{n}}, \quad (41)$$

where

$$B_{\mathbf{n}} = \sum_{k=1}^d \frac{1}{h_k} \left( \text{diag}_{j=1, \dots, n} b_k(x_j) \right) H_{\mathbf{n},k} \quad (42)$$

is the FD convection matrix, resulting from the FD discretization of the first-order term in (16), while

$$C_{\mathbf{n}} = \left( \text{diag}_{j=1, \dots, n} c(x_j) \right) \quad (43)$$

is the matrix resulting from the FD discretization of the lower-order term (the reaction term). We show that

$$\|n^{-2} B_{\mathbf{n}}\|_2 = o(\sqrt{N(\mathbf{n})}) \quad (44)$$

and

$$\{n^{-2} C_{\mathbf{n}}\}_n \sim_{\text{GLT}} 0 \quad (45)$$

To prove (44), we can notice that the matrices  $H_{\mathbf{n},k}$  are elementwise disjoint, meaning that

$$[H_{\mathbf{n},k}]_{i,j} \neq 0 \implies [H_{\mathbf{n},h}]_{i,j} = 0 \quad \forall h \neq k.$$

Consequently, for every  $d$ -uple of diagonal matrices  $D_k$  of size  $N(\mathbf{n})$ , we have

$$\left\| \sum_{k=1}^d D_k H_{\mathbf{n},k} \right\|_2^2 = \sum_{k=1}^d \|D_k H_{\mathbf{n},k}\|_2^2.$$

Let us keep in mind that the functions  $b_k(\mathbf{x})$  satisfy

$$|b_k(\mathbf{x})(x_1 \cdots x_d)^\alpha| \leq C, \quad \forall x > 0, \quad \forall k,$$

where  $C > 0$  is a constant.

$$\begin{aligned}
\|n^{-2}B_{\mathbf{n}}\|_2^2 &= \left\| \sum_{k=1}^d \frac{1}{n^2 h_k} \left( \text{diag}_{j=1, \dots, \mathbf{n}} b_k(x_j) \right) H_{\mathbf{n},k} \right\|_2^2 \\
&= \frac{1}{n^2} \sum_{k=1}^d \nu_k^2 \left\| \left( \text{diag}_{j=1, \dots, \mathbf{n}} b_k(x_j) \right) H_{\mathbf{n},k} \right\|_2^2 \\
&\leq \frac{2}{n^2} \sum_{k=1}^d \nu_k^2 \sum_{j=1}^{\mathbf{n}} b_k^2(x_j) \tag{46}
\end{aligned}$$

$$\begin{aligned}
&\leq \frac{2C^2}{n^2} \sum_{k=1}^d \nu_k^2 \sum_{j=1}^{\mathbf{n}} (j_1 h_1 \cdots j_d h_d)^{-2\alpha} \\
&= \left( \frac{2C^2}{n^{2-2d\alpha} N(\boldsymbol{\nu})^{-2\alpha}} \sum_{k=1}^d \nu_k^2 \right) \prod_{k=1}^d \sum_{j=1}^{n_k} j^{-2\alpha}. \tag{47}
\end{aligned}$$

If  $\alpha < 1/2$ , then  $|b_k(\mathbf{x})(x_1 \cdots x_d)^{1/2}| \leq |b_k(\mathbf{x})(x_1 \cdots x_d)^\alpha| \leq C$ , so we explore the case  $\alpha \geq 1/2$ .

- If  $\alpha = 1/2$ , then, owing to 47, we obtain

$$\begin{aligned}
\|n^{-2}B_{\mathbf{n}}\|_2^2 &\leq \left( \frac{2C^2}{n^{2-d} N(\boldsymbol{\nu})^{-1}} \sum_{k=1}^d \nu_k^2 \right) \prod_{k=1}^d \sum_{j=1}^{n_k} j^{-1} \\
&\leq \left( \frac{2C^2}{n^{2-d} N(\boldsymbol{\nu})^{-1}} \sum_{k=1}^d \nu_k^2 \right) \prod_{k=1}^d (1 + \log(n_k)) \tag{48}
\end{aligned}$$

$$= O(\log^{d/2}(n) n^{d/2-1}). \tag{49}$$

- If  $\alpha > 1/2$ , then referring to (47) and owing to (11), we obtain

$$\begin{aligned}
\|n^{-2}B_{\mathbf{n}}\|_2^2 &\leq \left( \frac{2C^2}{n^{2-2d\alpha} N(\boldsymbol{\nu})^{-2\alpha}} \sum_{k=1}^d \nu_k^2 \right) \prod_{k=1}^d \sum_{j=1}^{n_k} j^{-2\alpha} \\
&\leq \left( \frac{2C^2}{n^{2-2d\alpha} N(\boldsymbol{\nu})^{-2\alpha}} \sum_{k=1}^d \nu_k^2 \right) \prod_{k=1}^d \frac{-n_k^{-2\alpha+1} + 2\alpha}{2\alpha - 1} \\
&\leq \frac{2C^2}{N(\boldsymbol{\nu})^{-2\alpha}} \left( \sum_{k=1}^d \nu_k^2 \right) \left( \frac{2\alpha}{2\alpha - 1} \right)^d n^{-2+2d\alpha}. \tag{50}
\end{aligned}$$

We conclude that

$$\alpha \geq 1/2 \implies \|n^{-2}B_{\mathbf{n}}\|_2 = O(n^{-1+d\alpha}). \tag{51}$$

Observe that  $\frac{1}{d} + \frac{1}{2} > \alpha$  implies  $\|n^{-2}B_{\mathbf{n}}\|_2^2 = o(n^{d/2}) = o(\sqrt{N(\mathbf{n})})$ . Noting that

$$\{C_{\mathbf{n}}\}_n \sim_{\text{GLT}} c(\mathbf{x}), \quad \{n^{-1}I_{\mathbf{n}}\}_n \sim_{\text{GLT}} 0$$

and using the structure of algebra of GLT sequences, we infer that the property (45) is met.

*Step 2.* Consider the matrix  $K_n$ . By (24) and (41)-(43), we know that

$$\begin{aligned}
K_n &= \sum_{k=1}^d \frac{1}{h_k^2} \left( \text{diag}_{j=1, \dots, n} a_{kk}(x_{j+\mathbf{e}_k/2}) \right) K_{n,kk}^+ \\
&\quad + \sum_{k=1}^d \frac{1}{h_k^2} \left( \text{diag}_{j=1, \dots, n} a_{kk}(x_{j-\mathbf{e}_k/2}) \right) K_{n,kk}^- \\
&\quad + \sum_{\substack{h,k=1 \\ h \neq k}}^d \frac{1}{h_h h_k} \left( \text{diag}_{j=1, \dots, n} a_{hk}(x_{j+\mathbf{e}_h}) \right) K_{n,hk}^+ \\
&\quad + \sum_{\substack{h,k=1 \\ h \neq k}}^d \frac{1}{h_h h_k} \left( \text{diag}_{j=1, \dots, n} a_{hk}(x_{j-\mathbf{e}_h}) \right) K_{n,hk}^-. \tag{52}
\end{aligned}$$

In view of axiom **GLT 3**, all the diagonal matrix-sequences that appear in (52) belong to the class of GLT sequences. More precisely, we observe

$$\{\text{diag}_{j=1, \dots, n} a_{kk}(x_{j \pm \mathbf{e}_k/2})\}_n \sim_{\text{GLT}} a_{kk}(\mathbf{x}), \tag{53}$$

$$\{\text{diag}_{j=1, \dots, n} a_{hk}(x_{j \pm \mathbf{e}_h})\}_n \sim_{\text{GLT}} a_{hk}(\mathbf{x}). \tag{54}$$

Using the identities (34)-(35) and axiom **GLT 4**, we thus obtain

$$\{n^{-2}K_n\}_n \sim_{\text{GLT}} \sum_{k=1}^d \nu_k^2 a_{kk}(x)(2 - 2 \cos \theta_k) + \sum_{\substack{h,k=1 \\ h \neq k}}^d \nu_h \nu_k a_{hk}(x) \sin \theta_h \sin \theta_k, \tag{55}$$

that can be rewritten as

$$\{n^{-2}K_n\}_n \sim_{\text{GLT}} \boldsymbol{\nu}(\mathbf{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T.$$

Now  $n^{-2}(K_n + C_n)$  are Hermitian matrices, and since  $\{n^{-2}C_n\}_n$  is zero-distributed, by axioms **GLT 4** and **GLT 1** we infer

$$\{n^{-2}K_n + n^{-2}C_n\}_n \sim_{\text{GLT}, \sigma, \lambda} \boldsymbol{\nu}(\mathbf{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T.$$

Owing to (44), even the sequence  $\{n^{-2}B_n\}_n$  is zero-distributed, and hence again by axioms **GLT 4** and **GLT 1** we obtain

$$\{n^{-2}A_n\}_n = \{n^{-2}K_n + n^{-2}B_n + n^{-2}C_n\}_n \sim_{\text{GLT}, \sigma} \boldsymbol{\nu}(\mathbf{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T.$$

Finally, using Theorem 1.1 we conclude that

$$\{n^{-2}A_n\}_n = \{n^{-2}K_n + n^{-2}B_n + n^{-2}C_n\}_n \sim_{\lambda} \boldsymbol{\nu}(\mathbf{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T.$$

#### 4.4 A basic application in a preconditioning context

We start this subsection by coming back to the one-dimensional finite difference discretization considered in Subsection 4.1 for the problem

$$\begin{cases} -(a(x)u'(x))' + b(x)u'(x) + c(x)u(x) = f(x), & x \in (0, 1), \\ u(0) = \alpha, & u(1) = \beta, \end{cases}$$

where

- $a(x), c(x)$  are real-valued functions, continuous a.e., defined in  $[0, 1]$ ,
- $b(x)$  is a real-valued function on  $[0, 1]$ , such that  $|b(x)x^\alpha|$  is bounded for some  $\alpha < 3/2$ ,
- $f(x)$  is a general function.

After making the usual scaling by  $h^2$ , the matrix arising from the discretization of the second-order operator shows the form

$$A_n = A_n(a) = \begin{pmatrix} a_1 + a_3 & -a_3 & & & & \\ -a_3 & a_3 + a_5 & -a_5 & & & \\ & \ddots & \ddots & \ddots & & \\ & & -a_{2n-3} & a_{2n-3} + a_{2n-1} & -a_{2n-1} & \\ & & & -a_{2n-1} & a_{2n-1} + a_{2n+1} & \end{pmatrix},$$

while the matrices arising from the discretization of the lower order operators are

$$B_n = B_n(b) = \frac{h}{2} \begin{pmatrix} 0 & b_1 & & & \\ -b_2 & 0 & b_2 & & \\ & \ddots & \ddots & \ddots & \\ & & -b_{n-1} & 0 & b_{n-1} \\ & & & -b_n & 0 \end{pmatrix}, \quad C_n = C_n(c) = h^2 \operatorname{diag}(c_1, \dots, c_n).$$

Now let

$$Z_n = Z_n(a, b, c, h) = A_n(a) + B_n(b) + C_n(c)$$

be the global discretization matrix and let us consider the standard real-imaginary part representation [7]. Then

$$\begin{aligned} \Re(Z_n) &= A_n(a) + C_n(c) + \Re(B_n(b)), & \Im(Z_n) &= \Im(B_n(b)), \\ B_n(b) &= -h \operatorname{diag}(b_1, \dots, b_n) T_n(i \sin(\theta)). \end{aligned}$$

From Subsection 4.1 we recall that

$$\{A_n(a)\}_n \sim_{\text{GLT}} a(x)(2 - 2 \cos(\theta)), \quad \{B_n(b)\}_n \sim_{\text{GLT}} 0, \quad \{C_n(c)\}_n \sim_{\text{GLT}} 0,$$

and  $\{Z_n(a, b, c, h)\}_n \sim_\lambda a(x)(2 - 2 \cos(\theta))$ .

Now we make the problem even less Hermitian by considering the preconditioning by the positive definite Toeplitz matrices  $A_n(1) = K_n = T_n(2 - 2 \cos(\theta))$  (see equation (7)) of the matrices  $Z_n(a, b, c, h)$ . It is evident that  $\{K_n\}_n \sim_{\text{GLT}} 2 - 2 \cos(\theta)$  and hence, by the algebra structure of GLT sequences,

$$\{K_n^{-1} Z_n(a, b, c, h)\}_n \sim_{\text{GLT}} a(x).$$

In particular, we have  $\{K_n^{-1} Z_n(a, b, c, h)\}_n \sim_\sigma a(x)$ . However, for the convergence of a preconditioned Krylov method, it would be useful to have information on the eigenvalues and Theorem 1.1 is a possible tool. In the present context, the problem in using Theorem 1.1 relies on the fact the  $K_n^{-1}$  is dense and consequently it is difficult to evaluate any Schatten norm of its imaginary part. To work around this problem, we consider a symmetrization trick very popular for handling proofs in a preconditioning setting. In fact,  $K_n^{-1} Z_n(a, b, c, h)$  is similar to

$$K_n^{-1/2} Z_n(a, b, c, h) K_n^{-1/2}$$

so that for proving the eigenvalue distribution of  $\{K_n^{-1} Z_n(a, b, c, h)\}_n$  we can focus on the sequence

$$\{K_n^{-1/2} Z_n(a, b, c, h) K_n^{-1/2}\}_n.$$

Now  $K_n$  is positive definite and  $\{K_n\}_n$  is a GLT sequence with symbol  $2 - 2 \cos(\theta)$ . Therefore, the inverse of  $K_n$  and its square root are well defined and, again by the powerful properties of the GLT sequences (specifically, axioms **GLT 3**, **GLT 4**, **GLT 5**, **GLT 6**) the matrix-sequences  $\{K_n^{-1}\}_n$ ,  $\{K_n^{-1/2}\}_n$ , and

$$\{K_n^{-1/2} Z_n(a, b, c, h) K_n^{-1/2}\}_n$$

are GLT sequences with symbols  $1/(2 - 2 \cos(\theta))$ ,  $1/\sqrt{2 - 2 \cos(\theta)}$ , and  $a(x)$ , respectively. As a consequence, the singular value distribution results for the sequences  $\{K_n^{-1}\}_n$ ,  $\{K_n^{-1/2}\}_n$ , and

$$\{K_n^{-1/2} Z_n(a, b, c, h) K_n^{-1/2}\}_n$$

are obvious. The difficulty is that we are interested in the eigenvalue distribution of  $\{K_n^{-1/2}Z_n(a, b, c, h)K_n^{-1/2}\}_n$  and the involved matrices are non-Hermitian. Hence, in order to apply Theorem 1.1 in the most convenient way, we consider the real-imaginary part representation of  $K_n^{-1/2}Z_n(a, b, c, h)K_n^{-1/2}$ , that is,

$$\begin{aligned} K_n^{-1/2}Z_n(a, b, c, h)K_n^{-1/2} &= K_n^{-1/2}(A_n(a) + C_n(c) + \Re(B_n(b)))K_n^{-1/2} \\ &\quad - ihK_n^{-1/2}\Im(\text{diag}(b_1, \dots, b_n)T_n(i\sin(\theta)))K_n^{-1/2}. \end{aligned}$$

It is evident that  $R_n = K_n^{-1/2}(A_n(a) + C_n(c) + \Re(B_n(b)))K_n^{-1/2}$  is symmetric and that  $\{R_n\}_n \sim_{\text{GLT}} a(x)$ . Therefore it remains to study a proper Schatten norm of  $S_n = -hK_n^{-1/2}\Im(\text{diag}(b_1, \dots, b_n)T_n(i\sin(\theta)))K_n^{-1/2}$ , which is a simplified task since the perturbation matrix  $iS_n$  is skew-Hermitian (and hence normal) so that the singular values are the moduli of the eigenvalues. Indeed the key point here is that the matrix  $S_n$  is not easy to evaluate in terms of entries, but the spectrum can be evaluated and in fact this has been already done in [6, Theorems 3.1 and 3.7]. In these theorems, under the assumption that  $b$  is bounded, it is proved that the sequence  $\{S_n\}_n$  is properly clustered at zero in the eigenvalue sense and is spectral bounded. This means that for every  $\epsilon > 0$  there exists a nonnegative integer number  $N_\epsilon$  such that the number of eigenvalues exceeding in modulus  $\epsilon$  are bounded by  $N_\epsilon$ , and the spectral norm of  $S_n$  is bounded by a constant  $C$  independent of  $n$ . We are now in the position of applying Theorem 1.1 and in fact, for every  $\epsilon > 0$ , we obtain

$$\|S_n\|_2^2 \leq \|S_n\|^2 N_\epsilon + (n - N_\epsilon)\epsilon^2 \leq C^2 N_\epsilon + (n - N_\epsilon)\epsilon^2,$$

so that  $\|S_n\|_2 = o(\sqrt{n})$  by the arbitrariness of  $\epsilon$ . In conclusion, setting  $X_n = R_n$ ,  $Y_n = iS_n$ , and recalling that  $K_n^{-1/2}Z_n(a, b, c, h)K_n^{-1/2} = R_n + iS_n$ , Theorem 1.1 implies that  $\{K_n^{-1/2}Z_n(a, b, c, h)K_n^{-1/2}\}_n \sim_\lambda a(x)$ , that is, by similarity,

$$\{K_n^{-1}Z_n(a, b, c, h)\}_n \sim_\lambda a(x). \quad (56)$$

Before briefly giving the results in the multidimensional setting, we introduce a pair of general and useful tools for generalizing relation (56). The considered tools do not depend on the dimensionality of the underlying differential operator and hence they can be applied verbatim in the context of discretized PDEs.

**Theorem 4.1.** *Let  $S_n$  be either a Hermitian matrix or a skew-Hermitian matrix of size  $n$  and consider  $P_n^+$ ,  $P_n^-$  two positive definite matrices of size  $n$ . Take the preconditioned matrices  $F_n^+ = [P_n^+]^{-1}S_n$ ,  $F_n^- = [P_n^-]^{-1}S_n$  and sort the eigenvalues of  $vF_n^\pm$  in non-decreasing order, with  $v = 1$  if  $S_n$  is Hermitian and  $v = -i$  if  $S_n$  is skew-Hermitian, that is,*

$$\lambda_1(vF_n^\pm) \leq \dots \leq \lambda_n(vF_n^\pm).$$

*Under the assumption that  $P_n^+ \geq P_n^-$  (that is  $P_n^+ - P_n^-$  is positive semidefinite) we have*

$$|\lambda_j(vF_n^+)| \leq |\lambda_j(vF_n^-)|, \quad j = 1, \dots, n. \quad (57)$$

*Proof.* The proof consists in applying the minimax characterization

$$\lambda_j(vF_n^\pm) = \min_{\dim(V)=j} \max_{\mathbf{x} \in V, \mathbf{x} \neq 0} \frac{\mathbf{x}^* v S_n \mathbf{x}}{\mathbf{x}^* P_n^\pm \mathbf{x}}$$

and in observing that  $\mathbf{x}^* P_n^+ \mathbf{x} \geq \mathbf{x}^* P_n^- \mathbf{x} > 0$ , because  $P_n^+ - P_n^-$  is positive semidefinite and  $P_n^+$ ,  $P_n^-$  are positive definite).  $\square$

**Corollary 4.2.** *Under the very same assumptions and notations as in Theorem 4.1, we have*

$$\|F_{n,S}^+\|_p \leq \|F_{n,S}^-\|_p$$

for any  $p \in [1, \infty]$ , where

$$F_{n,S}^\pm = [P_n^\pm]^{-1/2} S_n [P_n^\pm]^{-1/2}.$$

*Proof.* The Schatten  $p$ -norm of a matrix is the  $l_p$ -norm of the vector of its singular values. Since  $F_{n,S}^\pm$  is Hermitian if and only if  $S_n$  is Hermitian and  $F_{n,S}^\pm$  is skew-Hermitian if and only if  $S_n$  is skew-Hermitian, it follows that the matrices  $F_{n,S}^\pm$  are normal and hence

$$\sigma_j(F_{n,S}^\pm) = |\lambda_j(F_{n,S}^\pm)|, \quad j = 1, \dots, n,$$

because  $F_{n,S}^\pm$  is similar to  $F_n^\pm$ . Given the above relations, the claimed thesis follows from (57).  $\square$

The consequences of the corollary above are quite strong. Take any  $\{P_n\}_n$  asymptotically equivalent to  $\{K_n\}_n$ , that is take any  $\{P_n\}_n$  such that each  $P_n$  is positive definite and there exist positive constants  $c$  and  $C$  independent of  $n$  for which

$$cK_n \leq P_n \leq CK_n.$$

Assume that  $\{P_n\}_n$  is a GLT sequence with symbol  $\phi(x, \theta)$  and consider the sequence  $\{Z_n(a, b, c, h)\}_n$ . We have the following:

- $P_n^{-1}Z_n(a, b, c, h)$  is similar to  $P_n^{-1/2}Z_n(a, b, c, h)P_n^{-1/2}$ ;
- $\{P_n^{-1}Z_n(a, b, c, h)\}_n$  is a GLT sequence with symbol

$$a(x)(2 - 2\cos(\theta))/\phi(x, \theta)$$

and therefore this function is also the singular value symbol;

- $\{P_n^{-1}\Re(Z_n(a, b, c, h))\}_n$  is a GLT sequence with symbol

$$a(x)(2 - 2\cos(\theta))/\phi(x, \theta)$$

and therefore this function is both the singular value and eigenvalue symbol, because

$$P_n^{-1}\Re(Z_n(a, b, c, h))$$

is similar to the Hermitian matrix

$$P_n^{-1/2}\Re(Z_n(a, b, c, h))P_n^{-1/2};$$

- finally, thanks to the spectral equivalence and to the crucial Corollary 4.2,  $\|P_n^{-1/2}\Re(Z_n(a, b, c, h))P_n^{-1/2}\|_p$  and  $\|K_n^{-1/2}\Re(Z_n(a, b, c, h))K_n^{-1/2}\|_p$  are asymptotically equivalent sequences with equivalence constants  $1/C$  and  $1/c$ .

As a consequence of the previous items, Theorem 1.1 can be applied with the same conclusions as in the basic case of  $P_n = K_n$  and hence

$$\{P_n^{-1}Z_n(a, b, c, h)\}_n \sim_\lambda \frac{a(x)(2 - 2\cos(\theta))}{\phi(x, \theta)}. \quad (58)$$

The interesting fact is that  $P_n$  can be chosen as  $D_n(a^{1/2})K_nD_n(a^{1/2})$  which is a positive definite matrix (the diffusion coefficient  $a(x)$  is positive). In this way, due to the structure of algebra of GLT sequences, the resulting sequence  $\{P_n\}_n$  is a GLT sequence with symbol  $\phi(x, \theta) = a(x)(2 - 2\cos(\theta))$ . Furthermore the two sequences  $\{P_n\}_n$  and  $\{K_n\}_n$  are asymptotically equivalent under the assumption that  $a(x)$  is positive. Consequently, looking at (58), the spectral symbol of  $\{P_n^{-1}Z_n(a, b, c, h)\}_n$  is exactly 1, which means that the eigenvalues are clustered at 1 in a weak sense (see the analysis of the strong clustering in [28] under the additional assumptions that  $a(x)$  is two times differentiable in  $[0, 1]$  and  $b(x) = c(x)$  identically zero).

The same steps can be applied verbatim in the multidimensional case. We consider the FD scheme for problem (16). As preconditioner, we consider, e.g., the positive definite matrix coming from the same discretization to the same problem in (16) with the advection-reaction coefficients set to zero. As diffusion matrix, instead of  $A(\mathbf{x})$  we consider  $\hat{A}(\mathbf{x})$ . The conclusions are that

$$\{P_n^{-1}A_n\}_n \sim_{\text{GLT}, \sigma} \frac{\boldsymbol{\nu}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T}{\boldsymbol{\nu}(\hat{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T} \quad (59)$$

and

$$\{P_n^{-1}A_n\}_n \sim_\lambda \frac{\boldsymbol{\nu}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T}{\boldsymbol{\nu}(\hat{A}(\mathbf{x}) \circ H(\boldsymbol{\theta}))\boldsymbol{\nu}^T} \quad (60)$$

using Theorem 1.1, by following exactly the same steps performed in the one-dimensional setting.

## 5 Numerical Experiments

We now perform several numerical experiments for confirming the conclusions of Theorem 1.1 and for showing that the same conclusions are observed in practice under weaker assumptions (see Conjecture 6.1). In particular, we consider the following settings.

1. We consider the differential equation (6) with unbounded coefficients  $a(x) = c(x) = -\log(1-x)$ ,  $b(x) = 1/\sqrt[4]{x^5}$ . We numerically show that for the matrices arising from the FD discretization described in Section 4.1, it holds that

$$\{A_n\}_n + \{B_n\}_n + \{C_n\}_n \sim_\lambda a(x)(2 - 2\cos(\theta)).$$

Moreover, we numerically show that for the matrices arising from the FE discretization described in Section 4.2, it holds that

$$\left\{ \frac{1}{n+1} A_n \right\}_n + \left\{ \frac{1}{n+1} B_n \right\}_n + \left\{ \frac{1}{n+1} C_n \right\}_n \sim_\lambda a(x)(2 - 2\cos(\theta)).$$

2. We consider the differential equation (6) with unbounded coefficients  $a(x) = c(x) = -\log(1-x)$ ,  $b(x) = 1/\sqrt[4]{x^3}$ . We numerically show that for the preconditioned matrices arising from the FD discretization as described in Section 4.4, it holds that

$$\{K_n^{-1} Z_n(a, b, c, h)\}_n \sim_\lambda a(x).$$

In the case when  $P_n = D_n(a^{1/2})K_n D_n(a^{1/2})$ , we also show that (58) holds, that is,

$$\{P_n^{-1} Z_n(a, b, c, h)\}_n \sim_\lambda 1.$$

3. We consider the differential equation (15) in two space dimensions, with unbounded coefficients  $a_{1,1}(x, y) = c(x, y) = 1/xy$ ,  $a_{2,2}(x, y) = -xy$ ,  $a_{1,2}(x, y) = x + y$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^3}$ . We numerically show that for the matrices arising from the FD discretization described in Section 4.3, it holds that

$$\{A_n\}_n \sim_\lambda \mathbf{1}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\mathbf{1}^T.$$

4. We consider the differential equation (15) in two space dimensions, with unbounded coefficients  $a_{1,1}(x, y) = a_{2,2}(x, y) = 1 + 1/\sqrt{x} + 1/\sqrt{y}$ ,  $c(x, y) = 1/xy$ ,  $a_{1,2}(x, y) = 0$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^3}$ . We numerically show that for the preconditioned matrices arising from the FD discretization as described in Section 4.4, it holds that

$$\{P_n^{-1} A_n\}_n \sim_\lambda 1.$$

The matrices  $B_n$  are the source of non-Hermitianity in every setting, so we can choose the functions  $b(x)$ ,  $b_1(x, y)$ ,  $b_2(x, y)$  the biggest possible in order to test the validity of Theorem 1.1. In fact, we notice that in the experiments the functions  $b$  always satisfy the minimal hypothesis given in the respective sections. In the bidimensional FD case, we have also chosen a system that is not coercive or elliptic at every point, so that the related problem will be foreign to most real applications; yet, the experiments will demonstrate that Theorem 1.1 holds true even when considering artificially difficult examples. Actually, we want to test if Theorem 1.1 still holds when the perturbation has an  $o(n)$  Schatten 1-norm instead of an  $o(\sqrt{n})$  Schatten 2-norm.

1. We consider again the differential equation (6). If  $b(x)$  has a singularity of order  $\alpha > -2$  at  $x = 0$ , then we obtain a perturbation whose Schatten 1-norm is of order  $o(n)$ . Therefore, we consider again the coefficients  $a(x) = c(x) = -\log(1-x)$  and we modify the perturbation  $b(x) = 1/\sqrt[4]{x^7}$ . We numerically show that for the matrices arising from the FD discretization described in Section 4.1, it holds that

$$\{A_n\}_n + \{B_n\}_n + \{C_n\}_n \sim_\lambda a(x)(2 - 2\cos(\theta)).$$

Moreover, we numerically show that for the matrices arising from the FE discretization as described in Section 4.2, it holds that

$$\left\{ \frac{1}{n+1} A_n \right\}_n + \left\{ \frac{1}{n+1} B_n \right\}_n + \left\{ \frac{1}{n+1} C_n \right\}_n \sim_\lambda a(x)(2 - 2\cos(\theta)).$$

2. We consider the differential equation (15), in two space dimensions. If  $b_k(\mathbf{x})$  have singularities of order  $\alpha > -\frac{3}{2}$  at zero, then we obtain a perturbation whose Schatten 1-norm is of order  $o(N(\mathbf{n}))$ . Therefore, we consider the coefficients  $a_{1,1}(x, y) = a_{2,2}(x, y) = 1/\sqrt{xy}$ ,  $c(x, y) = 1/xy$ ,  $a_{1,2}(x, y) = x + y$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^5}$ . We show that for the matrices arising from the FD discretization described in Section 4.3, it holds that

$$\{A_n\}_n \sim_\lambda \mathbf{1}(A(\mathbf{x}) \circ H(\boldsymbol{\theta}))\mathbf{1}^T.$$

The aim of the experiments is to show that the chosen sequences of matrices possess the declared spectral symbols. We will show that the portion of eigenvalues with non-negligible imaginary part tends to zero, and that the distributions of eigenvalues converge to the corresponding symbols.

## 5.1 Tables and Graphs

Since all the spectral symbols in our experiments are real functions, we are interested in evaluating the number of eigenvalues with a non-negligible imaginary part. We report the number of eigenvalues with imaginary part greater than a fixed threshold and their percentage with respect to the dimension of the linear system. In particular, we fix  $\varepsilon = 10^{-1}, 10^{-2}$  and consider each experiment with dimensions  $N = 50, 100, 200, 400, 800$ . In the bidimensional FD context, we take  $\mathbf{n} = (n, n)$  with  $n = 7, 10, 14, 20, 28, 40$ , in order to obtain  $N(\mathbf{n}) = n^2$  the closest possible to 50, 100, 200, 400, 800.

In Table 1 we clearly observe how the percentage of outliers tends to zero when the perturbation has order  $o(\sqrt{n})$ , in accordance with the theory. For the case of two dimensions, since the fineness parameter is  $n^{-1}$  and the dimension is  $n^2$ , the choice  $\varepsilon = 10^{-2}$  is not appropriate to see the convergence with  $n = 7, 10, 14, 20, 28, 40$ : however also in this case the trend is quite clear.

$N$		50	100	200	400	800
FD-1-dim	$\varepsilon = 10^{-1}$	4/8%	6/6%	10/5%	12/3%	14/1.75%

Table 1: Number and percentage of eigenvalues with imaginary part greater than  $\varepsilon$ . The coefficients used are  $a(x) = c(x) = -\log(1-x)$ ,  $b(x) = 1/\sqrt[4]{x^5}$  in FD-1-dim, FE settings, and  $a(x) = c(x) = -\log(1-x)$ ,  $b(x) = 1/\sqrt[4]{x^3}$  in both the monodimensional preconditioned cases. The bidimensional coefficients are  $a_{1,1}(x, y) = a_{2,2}(x, y) = 1 + 1/\sqrt{x} + 1/\sqrt{y}$ ,  $c(x, y) = 1/xy$ ,  $a_{1,2}(x, y) = 0$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^3}$  in the preconditioned setting, and  $a_{1,1}(x, y) = c(x, y) = 1/xy$ ,  $a_{2,2}(x, y) = -xy$ ,  $a_{1,2}(x, y) = x + y$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^3}$  in the FD-2-dim setting.

We now take the real parts of the eigenvalues in increasing order. If we plot the corresponding values, we see that they converge to an increasing rearrangement of their symbols. In the following graphs are reported the plots for the above problems and functions under consideration, with focus on particular points to observe the behavior closer. In order, the plots report the FD and FE cases, the bidimensional FD and the preconditioned FD methods. The red line is always the increasing sampling of the spectral symbol, and the blue lines are the plots of the real parts of the eigenvalues, that converge to the red line as  $N$  increases.

Figure 1: Plot of the real part of eigenvalues in FD-1-dim case against the rearranged symbol. The used coefficients are  $a(x) = c(x) = -\log(1 - x)$ ,  $b(x) = 1/\sqrt[4]{x^5}$ .

Figure 2: Plot of the real part of eigenvalues in FE case against the rearranged symbol. The used coefficients are  $a(x) = c(x) = -\log(1 - x)$ ,  $b(x) = 1/\sqrt[4]{x^5}$ .

Figure 3: Plot of the real part of eigenvalues in FD-2-dim case against the rearranged symbol. The used coefficients are  $a_{1,1}(x, y) = c(x, y) = 1/xy$ ,  $a_{2,2}(x, y) = -xy$ ,  $a_{1,2}(x, y) = x + y$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^3}$ .

Figure 4: Plot of the real part of eigenvalues in Prec case against the rearranged symbol. The used coefficients are  $a(x) = c(x) = -\log(1 - x)$ ,  $b(x) = 1/\sqrt[4]{x^3}$ .

In Table 2 we observe how the percentage of outliers tends to zero also when the perturbation has Schatten 1-norm of order  $o(n)$  but Schatten 2-norm which is not  $o(\sqrt{n})$ , thus violating the assumptions of Theorem 1.1. As expected, the convergence to zero is slower when compared with the previous experiments. In any case, the numerical results support the generalization of Theorem 1.1 stated in Conjecture 6.1 below. In this regard, we

note that the graphs for the real parts of the eigenvalues are omitted because they are almost identical to the ones reported above.

$N$		50	100	200	400	800
FD-1-dim	$\varepsilon = 10^{-1}$	8/16%	12/12%	18/9%	28/7%	40/5%
	$\varepsilon = 10^{-2}$	8/16%	14/14%	22/11%	34/8.5%	74/9.25%
FE	$\varepsilon = 10^{-1}$	6/12%	12/12%	18/9%	26/6.5%	40/5%

	$\varepsilon = 10^{-2}$	16/32.653%	24/24%	42/21.43%	64/16%	114/14.54%

Table 2: Number and percentage of eigenvalues with imaginary part greater than  $\varepsilon$ . The coefficients used are  $a(x) = c(x) = -\log(1-x)$ ,  $b(x) = 1/\sqrt[4]{x^7}$  in FD-1-dim, FE and Prec settings and  $a_{1,1}(x, y) = a_{2,2}(x, y) = 1/\sqrt{xy}$ ,  $c(x, y) = 1/xy$ ,  $a_{1,2}(x, y) = x + y$ ,  $b_1(x, y) = b_2(x, y) = 1/\sqrt[4]{(xy)^5}$  in FD-2-dim settings.

## 6 Conclusions

We have proved a result (Theorem 1.1) which allows one to compute the asymptotic spectral distribution of matrix-sequences that can be written as a non-Hermitian perturbation of a given Hermitian matrix-sequence. As shown in Corollary 2.9, this result provides a noteworthy extension of a previous theorem due to Leonid Golinskii and the second author [23, Theorem 3.4] (see also [20, Corollary 4.1]). In particular, as illustrated in this paper, we are now able to compute the asymptotic spectral distribution of PDE discretization matrices even in the case where the PDE coefficients possess minimal regularity properties (only  $L^1$  in the case of finite elements!). It is also worth noting that the proof of the new result has not involved any functional analysis argument, which means that the proof of [23, Theorem 3.4] can be performed through purely matrix analysis arguments as in this paper; in particular, there is no need to resort to Mergelyan's theorem.

Extensive numerical experiments have been discussed. What we have observed seems to indicate that our new result can be made even stronger, by considering the weaker condition  $\|Y_n\|_1 = o(n)$  used in [23] and simultaneously dropping the assumption of boundedness of the involved matrix-sequences as done in this note in Theorem 1.1. We therefore state the following conjecture, which can be viewed as a generalization of both Theorem 1.1 and Theorem 3.4 from [23].

**Conjecture 6.1.** *Let  $X_n$  be a Hermitian matrix of size  $n$ , with  $\{X_n\}_n \sim_\lambda f$ . If  $\|Y_n\|_1 = o(n)$  then*

$$\{X_n + Y_n\}_n \sim_\lambda f.$$
