

Title: Computational epidemics driven by data

Description:

Mathematical modeling of the spread of disease is a fairly mature field. However, the increasing volumes and the improved granularity of data puts different perspectives on modeling in epidemics. Computational models tend to become more complex, more detailed, and containing more information. But without sufficient data quality to drive the simulations, the accuracy may well be imaginary.

In this project we are interested in partially countering such issues by explicitly designing epidemiological models driven by data. Part of the work will be centered around a software SimInf, www.siminf.org, and we will be developing novel ways of expressing the dynamics of disease spread such that data may be more efficiently incorporated. Issues with parameterization will be one focus point, and clear trade-offs in simulation uncertainty will be another.

This project will center around the following:

- **Data-driven modeling:** With data of different qualities, being able to put a confidence value to different data streams becomes increasingly important. We are therefore interested in developing computational models which can effectively provide residuals relative to data-sets, and such that the fit/misfit can be judged. In an environment where risk is an important aspect, this is often measured in terms of probabilities and likelihoods.
- **Bayesian inference:** A consistent way to probabilistically incorporate data is via Bayesian modeling. This formally allows pieces of information to be meaningfully incorporated as they are available. However, for this flexibility to also be realized, the computational complexity of the model can generally not be arbitrary, and the data-to-model flow must be designed with care. Ideally, Bayesian models output probabilistic answers which aligns very well with decision processes.
