## Sequential Monte Carlo methods

Lecture 4 - The bootstrap particle filter

Johan Alenlöv, Uppsala University
2019-08-26

## Outline - Lecture 4

Aim: Derive our first sequential Monte Carlo method: the bootstrap particle filter.

## Outline:

1. A (hopefully) intuitive preview
2. The bootstrap particle filter
3. Resampling
4. A toy example and a real world application

## Particle filter preview

## A (hopefully) intuitive preview (I/III)

Consider a toy 1D localization problem.

Data

## Model

Dynamics:

$$
X_{t+1}=X_{t}+u_{t}+V_{t}
$$

where $X_{t}$ denotes position, $u_{t}$ denotes velocity (known), $V_{t} \sim \mathcal{N}(0,5)$ denotes an unknown disturbance.

Measurements:

$$
Y_{t}=h\left(X_{t}\right)+E_{t}
$$

where $h(\cdot)$ denotes the world model (here the terrain height) and $E_{t} \sim \mathcal{N}(0,1)$ denotes an unknown disturbance.

## A (hopefully) intuitive preview (I/III)

Consider a toy 1D localization problem.

Data

## Model

Dynamics:

$$
X_{t+1}=X_{t}+u_{t}+V_{t}
$$

where $X_{t}$ denotes position, $u_{t}$ denotes velocity (known), $V_{t} \sim \mathcal{N}(0,5)$ denotes an unknown disturbance.

Measurements:

$$
Y_{t}=h\left(X_{t}\right)+E_{t}
$$

where $h(\cdot)$ denotes the world model (here the terrain height) and $E_{t} \sim \mathcal{N}(0,1)$ denotes an unknown disturbance.

Task: Learn about the state $X_{t}$ (position) based on the measurements $y_{1: t}$ by computing the filter density $p\left(x_{t} \mid y_{1: t}\right)$.

## A (hopefully) intuitive preview (II/III)

## A (hopefully) intuitive preview (III/III)

Highlights two key capabilities of the PF:

1. Automatically handles an unknown and dynamically changing number of hypotheses (modes).
2. Works with nonlinear/non-Gaussian models.

## The bootstrap particle filter

## Nonlinear filtering problem

Recall that the nonlinear filtering problem amounts to computing the filter PDF $p\left(x_{t} \mid y_{1: t}\right)$ when the model is given by

$$
\begin{aligned}
X_{t+1} \mid\left(X_{t}=x_{t}\right) & \sim p\left(x_{t+1} \mid x_{t}\right), \\
Y_{t} \mid\left(X_{t}=x_{t}\right) & \sim p\left(y_{t} \mid x_{t}\right), \\
X_{0} & \sim p\left(x_{0}\right) .
\end{aligned}
$$

We have shown that the solution is

$$
\begin{aligned}
p\left(x_{t} \mid y_{1: t}\right) & =\frac{p\left(y_{t} \mid x_{t}\right) p\left(x_{t} \mid y_{1: t-1}\right)}{p\left(y_{t} \mid y_{1: t-1}\right)} \\
p\left(x_{t} \mid y_{1: t-1}\right) & =\int p\left(x_{t} \mid x_{t-1}\right) p\left(x_{t-1} \mid y_{1: t-1}\right) \mathrm{d} x_{t-1}
\end{aligned}
$$

## Nonlinear filtering problem

Recall that the nonlinear filtering problem amounts to computing the filter PDF $p\left(x_{t} \mid y_{1: t}\right)$ when the model is given by

$$
\begin{aligned}
X_{t+1} \mid\left(X_{t}=x_{t}\right) & \sim p\left(x_{t+1} \mid x_{t}\right), \\
Y_{t} \mid\left(X_{t}=x_{t}\right) & \sim p\left(y_{t} \mid x_{t}\right), \\
X_{0} & \sim p\left(x_{0}\right) .
\end{aligned}
$$

We have shown that the solution is

$$
\begin{aligned}
p\left(x_{t} \mid y_{1: t}\right) & =\frac{p\left(y_{t} \mid x_{t}\right) p\left(x_{t} \mid y_{1: t-1}\right)}{p\left(y_{t} \mid y_{1: t-1}\right)} \\
p\left(x_{t} \mid y_{1: t-1}\right) & =\int p\left(x_{t} \mid x_{t-1}\right) p\left(x_{t-1} \mid y_{1: t-1}\right) \mathrm{d} x_{t-1}
\end{aligned}
$$

Basic idea: Try to approximate $p\left(x_{t} \mid y_{1: t}\right)$ sequentially in time $t=0,1, \ldots$ using importance sampling!

## Particle filter - representation

The particle filter approximates $p\left(x_{t} \mid y_{1: t}\right)$ by maintaining an empirical distribution made up of $N$ samples (particles) $\left\{x_{t}^{i}\right\}_{i=1}^{N}$ and corresponding importance weights $\left\{w_{t}^{i}\right\}_{i=1}^{N}$

$$
\underbrace{\hat{p}^{N}\left(x_{t} \mid y_{1: t}\right)}_{\widehat{\pi}^{N}\left(x_{t}\right)}=\sum_{i=1}^{N} w_{t}^{i} \delta_{x_{t}^{i}}\left(x_{t}\right)
$$

The particle filter provides a well-founded way of exploring the state space using random simulation.

## Importance sampling reminder

## Algorithm 1 Importance sampler

1. Sample $x^{i} \sim q(x)$.
2. Compute the weights $\widetilde{w}^{i}=\widetilde{\pi}\left(x^{i}\right) / q\left(x^{i}\right)$.
3. Normalize the weights $w^{i}=\widetilde{w}^{i} / \sum_{j=1}^{N} \widetilde{w}^{j}$.

Each step is carried out for $i=1, \ldots, N$.

## Sampling from the proposal

We sample from the proposal

$$
q\left(x_{t} \mid y_{1: t}\right)=\sum_{i=1}^{N} \nu_{t-1}^{i} q\left(x_{t} \mid x_{t-1}^{i}, y_{t}\right)
$$

using a two step procedure:

1. Select one of the components

$$
a_{t}^{i} \sim \mathcal{C}\left(\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}\right) \quad \text { (categorical distribution) }
$$

## Sampling from the proposal

We sample from the proposal

$$
q\left(x_{t} \mid y_{1: t}\right)=\sum_{i=1}^{N} \nu_{t-1}^{i} q\left(x_{t} \mid x_{t-1}^{i}, y_{t}\right)
$$

using a two step procedure:

1. Select one of the components

$$
a_{t}^{i} \sim \mathcal{C}\left(\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}\right) \quad \text { (categorical distribution) }
$$

2. Generate a sample from the selected component,

$$
x_{t}^{i} \sim q\left(x_{t} \mid x_{t-1}^{a_{t}^{i}}, y_{t}\right)
$$

Repeat this $N$ times, for $i=1, \ldots, N$.

## Selecting the mixture components - resampling

The particle $\bar{x}_{t-1}^{i}=x_{t-1}^{a_{t}^{i}}$ is referred to as the ancestor of $x_{t}^{i}$, since $x_{t}^{i}$ is generated conditionally on $\bar{x}_{t-1}^{i}$.

The variable $a_{t}^{i} \in\{1, \ldots, N\}$ is referred to as the ancestor index, since it indexes the ancestor of particle $x_{t}^{i}$ at time $t-1$.

## Selecting the mixture components - resampling

The particle $\bar{x}_{t-1}^{i}=x_{t-1}^{a_{t}^{i}}$ is referred to as the ancestor of $x_{t}^{i}$, since $x_{t}^{i}$ is generated conditionally on $\bar{x}_{t-1}^{i}$.

The variable $a_{t}^{i} \in\{1, \ldots, N\}$ is referred to as the ancestor index, since it indexes the ancestor of particle $x_{t}^{i}$ at time $t-1$.

Sampling the $N$ ancestor indices

$$
a_{t}^{i} \sim \mathcal{C}\left(\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}\right), \quad i=1, \ldots, N
$$

is referred to as resampling.

## Selecting the mixture components - resampling

The particle $\bar{x}_{t-1}^{i}=x_{t-1}^{a_{t}^{i}}$ is referred to as the ancestor of $x_{t}^{i}$, since $x_{t}^{i}$ is generated conditionally on $\bar{x}_{t-1}^{i}$.

The variable $a_{t}^{i} \in\{1, \ldots, N\}$ is referred to as the ancestor index, since it indexes the ancestor of particle $x_{t}^{i}$ at time $t-1$.

Sampling the $N$ ancestor indices

$$
a_{t}^{i} \sim \mathcal{C}\left(\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}\right), \quad i=1, \ldots, N
$$

is referred to as resampling.
Resampling generates a new set of particles $\left\{\bar{x}_{t-1}^{i}\right\}_{i=1}^{N}$ by
sampling with replacement from among $\left\{x_{t-1}^{j}\right\}_{j=1}^{N}$, according to some weights $\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}$.

## Next step - computing the weights

## Algorithm 2 Importance sampler

1. Sample $x^{i} \sim q(x)$.
2. Compute the weights $\widetilde{w}^{i}=\widetilde{\pi}\left(x^{i}\right) / q\left(x^{i}\right)$.
3. Normalize the weights $w^{i}=\widetilde{w}^{i} / \sum_{j=1}^{N} \widetilde{w}^{j}$.

Each step is carried out for $i=1, \ldots, N$.

## Result - A first particle filter

## Algorithm 3 Bootstrap particle filter (for $i=1, \ldots, N$ )

1. Initialization $(t=0)$ :
(a) Sample $x_{0}^{i} \sim p\left(x_{0}\right)$.
(b) Set initial weights: $w_{0}^{i}=1 / N$.
2. for $t=1$ to $T$ do
(a) Resample: sample ancestor indices $a_{t}^{i} \sim \mathcal{C}\left(\left\{w_{t-1}^{j}\right\}_{j=1}^{N}\right)$.
(b) Propagate: sample $x_{t}^{i} \sim p\left(x_{t} \mid x_{t-1}^{i_{t}^{i}}\right)$.
(c) Weight: compute $\widetilde{w}_{t}^{i}=p\left(y_{t} \mid x_{t}^{i}\right)$ and normalize

$$
w_{t}^{i}=\widetilde{w}_{t}^{i} / \sum_{j=1}^{N} \widetilde{w}_{t}^{j} .
$$

## SMC structure

Same structure for all SMC algorithms.
For the bootstrap PF, given $\left\{x_{t-1}^{i}, w_{t-1}^{i}\right\}_{i=1}^{N}$ :
Resampling: $a_{t}^{i} \sim \mathcal{C}\left(\left\{w_{t-1}^{j}\right\}_{j=1}^{N}\right)$.
Propagation: $x_{t}^{i} \sim p\left(x_{t} \mid x_{t-1}^{a_{t}^{i}}\right)$.
Weighting: $\widetilde{w}_{t}^{i}=p\left(y_{t} \mid x_{t}^{i}\right)$ and normalize.
The result is a new weighted set of particles $\left\{x_{t}^{i}, w_{t}^{i}\right\}_{i=1}^{N}$.

## Intermediate approximations

Approximation of filtering distribution at time $t-1$ :

$$
\sum_{i=1}^{N} w_{t-1}^{i} \delta_{x_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)
$$

For the bootstrap particle filter:

- After resampling: $\frac{1}{N} \sum_{i=1}^{N} \delta_{\bar{x}_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)$.

## Intermediate approximations

Approximation of filtering distribution at time $t-1$ :

$$
\sum_{i=1}^{N} w_{t-1}^{i} \delta_{x_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)
$$

For the bootstrap particle filter:

- After resampling: $\frac{1}{N} \sum_{i=1}^{N} \delta_{\bar{x}_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)$.
- After propagation: $\frac{1}{N} \sum_{i=1}^{N} \delta_{x_{t}^{\prime}}\left(x_{t}\right) \approx p\left(x_{t} \mid y_{1: t-1}\right)$.

## Intermediate approximations

Approximation of filtering distribution at time $t-1$ :

$$
\sum_{i=1}^{N} w_{t-1}^{i} \delta_{x_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)
$$

For the bootstrap particle filter:

- After resampling: $\frac{1}{N} \sum_{i=1}^{N} \delta_{\bar{x}_{t-1}^{i}}\left(x_{t-1}\right) \approx p\left(x_{t-1} \mid y_{1: t-1}\right)$.
- After propagation: $\frac{1}{N} \sum_{i=1}^{N} \delta_{x_{t}^{i}}\left(x_{t}\right) \approx p\left(x_{t} \mid y_{1: t-1}\right)$.
- After weighting: $\sum_{i=1}^{N} w_{t}^{i} \delta_{x_{t}^{i}}\left(x_{t}\right) \approx p\left(x_{t} \mid y_{1: t}\right)$.

Examples

## An LG-SSM example (I/II)

Whenever you are working on a nonlinear inference method, always make sure that it solves the linear special case first!

## An LG-SSM example (I/II)

Whenever you are working on a nonlinear inference method, always make sure that it solves the linear special case first!

Consider the following LG-SSM (simple 1D positioning example)

$$
\begin{aligned}
\left(\begin{array}{c}
X_{t}^{\text {pos }} \\
X_{t}^{\text {vel }} \\
X_{t}^{\text {acc }}
\end{array}\right) & =\left(\begin{array}{ccc}
1 & T_{s} & T_{s}^{2} / 2 \\
0 & 1 & T_{s} \\
0 & 0 & 1
\end{array}\right)\left(\begin{array}{c}
X_{t-1}^{\text {pos }} \\
X_{t-1}^{\text {vel }} \\
X_{t-1}^{\text {acc }}
\end{array}\right)+\left(\begin{array}{c}
T_{s}^{3} / 6 \\
T_{s}^{2} / 2 \\
T_{s}
\end{array}\right) V_{t}, & V_{t} \sim \mathcal{N}(0, Q) \\
Y_{t} & =\left(\begin{array}{lll}
1 & 0 & 0 \\
0 & 0 & 1
\end{array}\right)\left(\begin{array}{c}
X_{t}^{\text {pos }} \\
X_{t}^{\text {vel }} \\
X_{t}^{\text {acc }}
\end{array}\right)+E_{t}, & E_{t} \sim \mathcal{N}(0, R)
\end{aligned}
$$

The Kalman filter provides the true filtering density, which implies that we can compare the PF to the truth in this case.

## An LG-SSM example (II/II)

Using 200 particles.

Using 20000 particles.

The particle filter estimates converge as the number of particles tends to infinity (Lecture 5).

## Nonlinear real-world application example

Aim: Compute the position of a person moving around indoors using sensors (inertial, magnetometer and radio) located in an ID badge, and a map.

The sensors (IMU and radio) and the DSP are mounted inside an ID badge.

## Application - indoor localization (II/III)

"Likelihood model" for an office environment, the bright areas are rooms and corridors (i.e., walkable space).

An estimated trajectory and the particle cloud visualized at a particular instance.

## Application - indoor localization (III/III)

## Show movie

RJohan Kihlberg, Simon Tegelid, Manon Kok and Thomas B. Schön. Map aided indoor positioning using particle filters. Reglermöte (Swedish Control Conference), Linköping, Sweden, June 2014.

## Use of random numbers in the particle filter

Random numbers are used to

1. initialize
2. resample and
3. propagate
the particles.
The weighting step does not require any new random numbers, it is just a function of already existing random numbers.

We can reason about and make use of the joint probability distribution of these random variables, from which the particle filter generates one realization each time it is executed.

## A few concepts to summarize lecture 4

Bootstrap particle filter: A particle filter with a specific choice of proposals. Particles are simulated according to the dynamical model and weights are assigned according to the measurement likelihood.

Resampling: The procedure that generates a new set of particles $\left\{\bar{x}_{t-1}^{i}\right\}_{i=1}^{N}$ by sampling with replacement from among $\left\{x_{t-1}^{j}\right\}_{j=1}^{N}$, according to some weights $\left\{\nu_{t-1}^{j}\right\}_{j=1}^{N}$.
Ancestor indices: Random variable that are used to make the stochasticity of the resampling step explicit by keeping track of which particles that get resampled.
